
Abstract

Context. Prioritization is essential part of requirements engineering, software release planning and many other software engineering disciplines. Cumulative Voting (CV) is known as relatively simple method for prioritizing requirements on a ratio scale. Historically, CV has been applied in decision making in government elections, corporate governance, and forestry. CV prioritization results are special type of data – compositional data.

Objectives. The purpose of this study is to aid decision making by collecting knowledge on the empirical use of CV and developing a method for detecting prioritization items with equal priority.

Methods. We present a systematic literature review of CV and CV result analysis methods. The review is based on search in electronic databases and snowball sampling of the primary studies. Relevant studies are selected based on titles, abstracts, and full text inspection. Additionally, we propose Equality of Cumulative Votes (ECV) – a CV result analysis method that identifies prioritization items with equal priority.

Results. CV has been used in not only in requirements prioritization and release planning but also in software process improvement, change impact analysis, model driven software development, etc. The review has resulted in a collection of state of the practice studies and CV result analysis methods. ECV has been applied to 27 prioritization cases from 14 studies and has identified nine groups of equal items in three studies.

Conclusions. We believe that collected studies and CV result analysis methods can help the adoption of CV prioritization method. The evaluation of ECV indicates that it is able to detect prioritization items with equal priority.

1. Introduction

Software products are becoming larger and more complex. Each product is usually affected by large number of factors such as product functional requirements, quality attributes, or software process improvement issues. Since time, funding, and resources are limited, it is seldom possible or efficient to fully address all the factors. Therefore, the level of attention to a particular factor must be decided according to its importance (i.e. business value), cost, risk, volatility, dependencies between the factors and many other criteria. These decisions are made by product stakeholders: users, clients, managers, sponsors, developers, and many other persons associated with the product. In order to make decisions regarding a large number of factors it is highly advisable to prioritize the factors in a systematic way [1].

One of the prioritization methods used in software engineering is Cumulative Voting (CV) [2]. The main advantage of CV is that it is relatively simple and fast yet produces priorities in ratio scale [1, 3]. This allows not only to determine what prioritization items are more important but also how much more important they are. Ratio scale prioritization is particularly important in software release planning and cost-value analysis [4, 5].

Prioritization is usually performed by multiple stakeholders, and individual priorities are combined into a single priority list. Each stakeholder's preferences may have different weight in the final priority. Such prioritization gives more information than just the priorities of factors. It may be useful to analyze the results of the prioritization to assess disagreement between stakeholders, measure stakeholder satisfaction with the results or find distinct groups of stakeholders.

The purpose of this study is to help industry practitioners and academia researchers in adopting and using CV. Importance of the prioritization in software engineering and prospectiveness of CV constitutes the need to do further research in this area.

This study presents a systematic literature review of the empirical use of CV and CV result analysis methods. A new method for CV result analysis, called Equality of Cumulative Votes (ECV), is proposed. The method identifies prioritization items with equal priority. ECV is evaluated using a considerable amount of data, which was obtained from the primary studies identified by the systematic review.

This remainder of this paper is structured as follows. The background is presented in Section 2. Section 3 describes related studies. In Section 4 research questions and methods are presented. The design of the systematic review is presented in Section 5 and ECV is presented in Section 6. Section 7

40 presents the results of the study and Section 8 is a discussion section.

41 **2. Background**

42 This section introduces the background of the study: description of soft-
43 ware requirements prioritization methods; examples of CV result analysis
44 methods; and description of compositional data analysis and CV.

45 *2.1. Prioritization Methods*

46 Some of the most popular prioritization methods are the analytical hi-
47 erarchy process (AHP), cumulative voting (CV), ranking, numerical assign-
48 ment, top-ten, the planning game, minimal spanning tree, bubble sort, bi-
49 nary search tree [1, 6]. Ranking and numerical assignment methods perform
50 prioritization on an ordinal scale. AHP and CV are harder to use and con-
51 sidered more time consuming compared to other methods but, on the other
52 hand, produce priorities in ratio scale.

53 Prioritization can be used not just to decide which factors to address,
54 but also to determine the order in which they need to be handled. In market
55 driven software development a small part of a very large number of require-
56 ments needs to be selected and divided into several releases to maximize
57 return on investment. In bespoke requirements, focusing on early delivery of
58 value can help reduce the risk of project cancellation.

59 Ratio scale priorities have several advantages over ordinal scale priori-
60 ties. Ratio scale shows not just the order of items but also relative distance
61 between them. This enables the priority of a group of items to be calculated
62 by summing up the priorities of individual items [4]. It is possible to say
63 that one item or set of items has higher priority than another set of items.
64 Supposing stakeholders have to choose between several lower priority items
65 and one item with higher priority; with ordinal scale, the item with high-
66 est priority will always be selected first. However, if priorities are given on
67 a ratio scale, it is possible that lower priority items will be selected if their
68 cumulative priority is higher. Knowing the relative importance of sets of pri-
69 oritization items helps in software release planning. Ratio scale allows the
70 combining of multiple priority factors by calculating ratios between them.
71 One example of this is the cost-value ratio that shows which requirements
72 give more value for less money [5].

73 *2.2. Prioritization Result Analysis*

74 Different studies use and analyze CV in different ways. Disagreement
75 between stakeholders happens when two or more stakeholders have assigned

76 a different priority to one prioritization item. If the level of disagreement is
77 high it may indicate potential conflicts between stakeholders. Such conflicts
78 may be of technical character, as well as social or cultural.

79 The satisfaction of a stakeholder with the final prioritization results is
80 determined by the difference between the results and the individual priorities
81 of the stakeholder. A smaller level of difference leads to higher satisfaction.
82 In the end, stakeholder satisfaction is important because it is necessary to
83 achieve stakeholder commitment.

84 A part of stakeholders may form a group of some kind and, therefore, pri-
85 oritize requirements similarly. Such groups may be formed by users, software
86 developers, managers and many other stakeholders. It may be useful to de-
87 tect whether a group of stakeholders has different preferences than all other
88 stakeholders. In [7] domain experts, technical experts, managers, project
89 managers, testers, and developers use CV to prioritize software process im-
90 provement issues. CV results are analyzed using disagreement charts and
91 satisfaction charts. Principal component analysis (PCA) is used to identify
92 distinct groups of stakeholders.

93 The same items can be prioritized by the same stakeholders multiple
94 times from different perspectives. It is useful to determine correlation be-
95 tween the priorities in different perspectives to assess the differences between
96 the perspectives. In [8] CV is used by developers, testers, and managers
97 to prioritize quality attributes. The same quality attributes are prioritized
98 from two perspectives: the perceived situation today and the perceived ideal
99 situation. Correlation between the two perspectives is evaluated using the
100 Spearman rank correlation matrix. This allows an analysis of how well the
101 company balances the priorities of software quality attributes.

102 In [9] change impact issues are prioritized by developers, testers, man-
103 agers, and system architects. The prioritization is done with respect to three
104 perspectives: strategic, tactical, and operative. In order to determine corre-
105 lation between the perspectives, CV results are analyzed using the Kruskal-
106 Wallis test. In [10] the results of [9] are analyzed using PCA, biplot, and
107 ternary plot. PCA is used to find correlated issues. Biplot shows variance,
108 correlation, and difference between the priorities of issues, and shows the
109 viewpoints of stakeholders. Ternary plot is used to show the relative number
110 of issues that received high, medium, and low priority.

111 2.3. Cumulative Voting

112 CV is a prioritization method for prioritizing a list of items [2]. CV has
113 many synonyms in literature: hundred dollar method, hundred dollar test,
114 hundred point method, 100\$ dollar method, 100\$ dollar test, 100\$ point

method. Before being applied in software engineering CV was used for political elections [11] and corporate governance [12]. CV is also applied in decision making in forestry [13], voting in social networks [14] and in computer algorithms for consensus clustering [15] e.g. clustering is the assignment of objects to groups and it is used in pattern recognition, data mining, and machine learning. Consensus clustering is a method for combining the results of different clustering algorithms.

In CV a stakeholder is given 100 points, imaginary dollars or units of percentages that can be spent on the prioritization items. The stakeholder can spend any amount of points on any number of items as long as the total amount adds up to 100. The more points assigned to an item, the higher the priority of the item. The stakeholder may spend all the points on just one item or distribute them among all or some of the items.

Often prioritization is done by more than one stakeholder. The final priority of an item can be calculated by adding up the points each stakeholder has spent on it. Sometimes the vote of some stakeholders may be more important than the votes of others. For example, a manager may be more influential than an employee or shareholders may have different amount of shares. In such a case the priorities of each stakeholder may be multiplied by an individual coefficient or a different amount of points for prioritization.

It is advisable to randomize the order of items in a prioritization list. This is necessary to minimize the effect of order on the prioritization results [16].

2.3.1. *Benefits and Drawbacks of Cumulative Voting*

Compared to AHP, CV is faster and easier to learn and use [1, 3]. AHP benefits from consistency check, but CV does not require this because all prioritization items are evaluated simultaneously [3].

There are a few problems with CV. First of all, it cannot be repeated for the same stakeholders and prioritization items due to stakeholder bias [2] (c.f. Section 2.3.4). Secondly, CV becomes more difficult if the number of prioritization items increases [17].

2.3.2. *Example of Cumulative Voting by Several Stakeholders*

Let us give an example of CV with several stakeholders. Suppose Robin, Alice, and John are three friends who want to buy some beverages in a store. They have different preferences but do not want to buy too many drinks. Therefore, they decide to use CV to decide what to buy. Each of the friends distributes 100 points between four items: milk, tea, coffee, and juice (Step 1 in Figure 1). Each of them will spend a different amount of money on

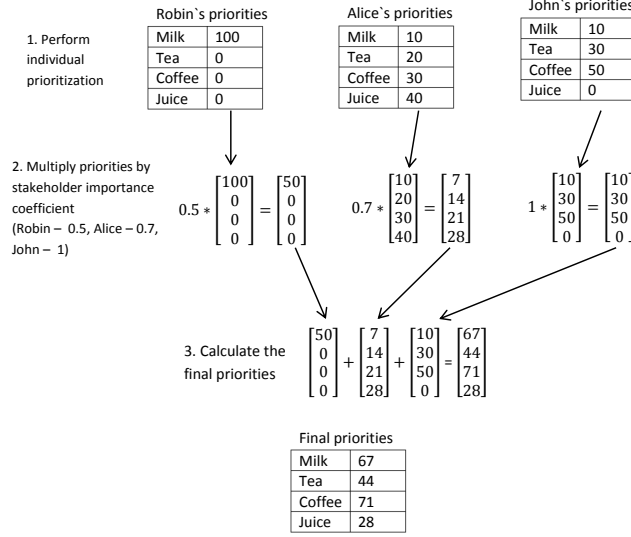

Figure 1: Example of Cumulative Voting Performed by Several Stakeholders

the purchase, hence, their priorities are multiplied by different coefficients (Step 2 and the stakeholder importance coefficient in Figure 1). The final beverage priorities are calculated by summing up the weighted priorities of stakeholders (Step 3 in Figure 1).

2.3.3. Stakeholder Bias

Prioritization using CV may be biased if a stakeholder knows the preferences of other stakeholders. He may manipulate the results by spending more points on items that are important to him but not the other stakeholders. On the one hand, stakeholder bias makes it unreasonable to repeat CV with the same prioritization items and stakeholders. On the other hand, this property of CV may be useful in giving more power to important minority stakeholders, such as security experts or software testers. Suppose the same software requirements are prioritized for a second time using CV. A developer knows that all vital functionality is selected by other stakeholders, but his toy feature is left out. The developer could spend all his points on this feature to put it in the next release.

Stakeholder bias may be mitigated by setting a maximum priority that can be assigned to an item. This way each stakeholder is forced to distribute the money between several prioritization items [4].

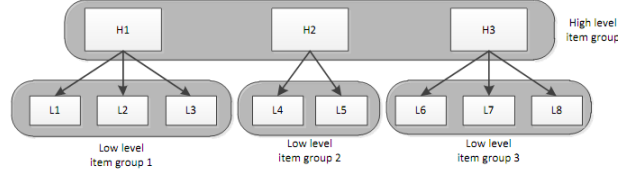

Figure 2: Prioritization Item Hierarchy Example

Another bias is that people in general tend to assign round priority values. This is caused by lack of objective judgement criteria. Either way it seems to be a minor problem because all prioritization is largely based on expert opinion.

2.3.4. Scalability of Cumulative Voting, Hierarchical Cumulative Voting

Standard CV approach has a low scalability. If the number of prioritization items is high, stakeholders may lose sight of the bigger picture and assign priorities to a limited number of items. A partial solution to the problem is giving more points for prioritization (1,000 or 10,000 instead of 100).

When the number of prioritization items is high they can usually be grouped hierarchically by forming a tree structure (Figure 2) and, thus, parent-child dependencies will exist between many items.

In [4] the authors propose a method for prioritizing hierarchically structured items called Hierarchical Cumulative Voting (HCV). It may be seen as combination of the hierarchical part of the Analytical Hierarchy Process (AHP) [1, 18] and the CV prioritization method. Since items are prioritized in smaller sets, stakeholders do not lose sight of the bigger picture during prioritization, and the prioritization of a large number of requirements is considered easier.

2.3.5. Compensation Factor

HCV deals with the problem of prioritization scalability but it comes at a cost. Low level item groups may consist of different number of items, but the number of points spent on each group is the same, i.e. in a small-sized group, the same amount of points is distributed among fewer items. Hence, items in smaller groups are statistically more likely to have a higher priority on average than items in larger groups. To balance this difference each low level prioritization item can be multiplied by a compensation factor [4].

One example of compensation factors is the number of items in small-sized requirement groups as explained above. However, this compensation

202 factor has a major drawback. In extreme cases it favours items in larger
 203 groups over items in smaller ones. For instance, suppose an item (A) in a
 204 group of 10 items is assigned 60 points. Hence, A will receive 600 compen-
 205 sated points. In this case it is impossible for any item in a group smaller
 206 than 6 items to compete with A . Even if item (B) in a group of 5 is assigned
 207 the maximum number of points (100), the maximum compensated priority
 208 value B can receive is 500.

209 In [17] the authors suggest that compensated prioritization is favourable
 210 over uncompensated. But neither compensated nor uncompensated prior-
 211 itization is perfect and as a general rule it is better to keep the size of
 212 prioritization item groups similar.

213 2.3.6. HCV Execution

214 According to [4] HCV is conducted with the following steps (Steps 4 and
 215 5 are optional):

- 216 1. Construct hierarchy. Prioritization items need to be divided into one
 217 high and several low level item groups. Each low level item group is
 218 child to exactly one high level item. And each high level item has
 219 one low level item group. One low level item may belong to several
 220 item groups. Even if part of the items are not logically connected
 221 they can be grouped separately and assigned a fake parent item, e.g.
 222 ‘misc. items’. HCV does not provide any directions on creating a
 223 requirements hierarchy.
- 224 2. Each high and low level item group is prioritized separately using CV.
 225 The stakeholder may prioritize all item groups at once or one by one.
 226 But it should be possible to prioritize groups in any order and repeat-
 227 edly, because the stakeholder might learn more about the items while
 228 performing the prioritization.
 229 In particular he is likely to learn more about a high level item when
 230 prioritizing its low level item group [19]. Some stakeholders may pri-
 231 oritize only part of the groups and each group may be prioritized by
 232 different stakeholders.
- 233 3. Priority of each low level item is normalized by dividing it with the
 234 sum of all low level priorities of items in all groups:

$$p_{i\text{normalized}} = \frac{p_i}{\sum_{j=0}^n p_j} \quad (1)$$

- 235 4. The final priority of each low level item is calculated by multiplying it
 236 with the priority of its parent high level item.

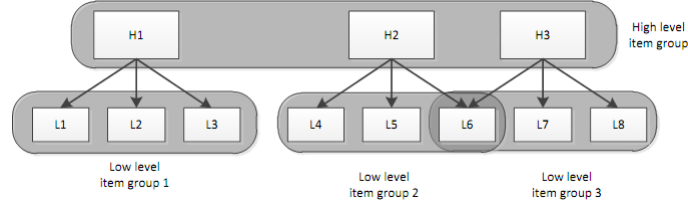

Figure 3: Overlapping Prioritization Item Hierarchy Example

- 237 5. Apply the compensation factor to all low level requirements as de-
238 scribed in Section 2.3.5.
- 239 6. When multiple stakeholders have performed the prioritization, priori-
240 ties of low level items are combined as in standard CV.

241 It is possible that one low level item is child of more than one high
242 level requirement and, thus, belongs to two or more low level requirement
243 groups (see Figure 3). Such requirements participate in the standard HCV
244 prioritization process and are prioritized two or more times with each group
245 they belong to. At the end of the prioritization they receive several priority
246 values. These values must be summed together to form the final priority
247 of the item. (This is done because the item adds value to both parts of
248 hierarchy.)

249 2.3.7. Example of Hierarchical Cumulative Voting

250 In this section we will give a short example of HCV. Suppose six require-
251 ments for a mobile phone operating system need to be prioritized: ‘reminder
252 alarm’, ‘specify repeated event’, ‘hide contact’, ‘add picture to phonebook’,
253 ‘search contact’, ‘make video call’. Three high level requirements can be
254 identified: ‘Calendar’, ‘Phonebook’, ‘Call’. The low level requirements are
255 then grouped as sub-requirements of high level requirements as shown in
256 Figure 4. The ‘Search contact’ requirement is a sub-requirement and has
257 two parent requirements— ‘Phonebook’ and ‘Call’. The computation of the
258 final priorities of requirements is shown in Table 1.

259 After requirements are grouped, and a hierarchy is defined, each group of
260 requirements are then prioritized using CV. The final priority of a low level
261 requirement is computed by multiplying the priority of the requirement with
262 the priority of its parent high level requirement and the compensation factor.
263 The compensation factor in this particular case is the number of elements in
264 a group, two for the ‘calendar’ and ‘call’ sub-requirements and three for the
265 ‘phonebook’ sub-requirements.

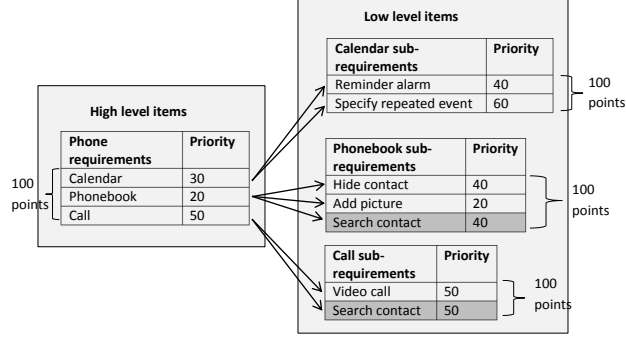

Figure 4: Example of Hierarchical Cumulative Voting, Requirement Hierarchy

Table 1: Example of Hierarchical Cumulative Voting

Phone requirements	Compensation factor	Sub-requirements	Priority calculation	Final priority
Calendar	2	Reminder alarm	$40 \times 30 \times 2$	2400
Calendar	2	Specify repeated event	$60 \times 30 \times 2$	3600
Phonebook	3	Hide contact	$40 \times 20 \times 3$	1600
Phonebook	3	Add picture	$20 \times 20 \times 3$	800
Phonebook & Call	3 & 2	Search contact	$40 \times 20 \times 3 + 50 \times 50 \times 2$	7400
Call	2	Video call	$50 \times 50 \times 2$	2500

2.4. Compositional Data Analysis

CV results can be seen as a special type of data—compositional data. Compositional data does not contain absolute values. It shows only the relative weight of a component in a whole. In [10] the authors propose the use of compositional data analysis for the statistical analysis of CV.

A compositional data item is a vector (x) of positive components with a constant sum k :

$$x = (X_1; X_2; \dots; X_n) \text{ where } x_i \geq 0 \text{ and } \sum_{j=1}^n x_j = k \quad (2)$$

The property of the sum of the items being restricted is called the constant sum constraint. In CV, priorities assigned by a stakeholder to the items of a prioritization set is a compositional data vector with a constant sum of 100. The value of k (i.e. 100 in this case) is arbitrary and does not affect the analysis of the data because the information is contained in the ratios between the components of the vector. The vector can sum up to any

number but still hold the same data, i.e. vectors (1, 2, 7) and (10, 20, 70) are in this case considered equivalent.

The priority of an item is relative to the priority of the other items in the set. Hence, the priority of an individual item is meaningless without context, i.e. the complete set of items. The same item may receive different priority when put in two different prioritization sets. If the item is put in a set of items with high priority it will receive lower relative priority. This also holds true the other way around; if the item is put in a set with low priority items its priority will be higher.

Compositional data analysis has, however, serious limitations. Ordinary unconstrained variables are free to take any positive or negative values, whereas, compositional data values can only be positive and have a constrained maximum value. Moreover, components of compositional data vectors are not independent from each other. The fact that an item is assigned 70 priority points means that the next item can take only values between 0 and 30. Hence, there is a negative correlation between the items.

Standard parametric statistical tests require that data vectors have multivariate normal distribution. Vector $X = (X_1, X_2, \dots, X_n)$ is considered to have multivariate normal distribution if any linear combination of its parts is normally distributed. Linear combination is defined by:

$$Y = a_1X_1 + a_2X_2 + \dots + a_nX_n \quad (3)$$

where Y is the product of lineal combination and a_i is any real number. Since the sum of priorities assigned in CV must add up to 100 (or any other constant number) at least one linear combination of X is not normally distributed because it must always add up to 100:

$$Y = 1 \cdot X_1 + 1 \cdot X_2 + \dots + 1 \cdot X_n = 100 \quad (4)$$

In our opinion, the above shows that CV results do not follow a multivariate normal distribution and, hence, means that they must not be analysed using parametric statistical tests [20].

2.4.1. Problem of Zeroes

Compositional data analysis requires that ratios between any components in a vector can be computed. Computing a ratio with a zero value is meaningless. This causes a problem because CV allows stakeholders to assign zero priorities to some prioritization items. There are two types of zeroes in compositional data: essential and rounded.

308 Essential zeroes mean that a data component is not present. Rounded
 309 zeroes mean that the component is present but its value is very low. We can
 310 assume that zeroes in CV results are rounded because the priority of an item
 311 is a completely abstract notion and the instrument for measuring priority is
 312 human judgement [10].

313 Before compositional data analysis can be applied to CV results, we must
 314 first remove zeroes in the data. One approach can be to forbid stakeholders
 315 to assign zero priorities. This approach is used in e.g. [7]. But this can
 316 add some unnecessary complexity to the prioritization process. In [10] the
 317 authors propose the use of a multiplicative replacement strategy (as defined
 318 in [21]) for CV result analysis.

319 This method replaces rounded zeroes with small values using the expres-
 320 sion

$$r_j = \begin{cases} \delta_j, & \text{if } x_j = 0, \\ (1 - \frac{\sum_{k|x_k=0} \delta_k}{c})x_j, & \text{if } x_j > 0, \end{cases} \quad (5)$$

321 where δ_j is the imputed value and c is the constant sum constraint (the
 322 same as k in equation (2)). In order for the total sum of components to stay
 323 constant the equation subtracts some value from the items with a priority
 324 higher than zero. More is subtracted from components with higher values
 325 than from the components with lower values and the value of the imputed
 326 δ_j is arbitrary.

327 2.4.2. Isometric Log-Ratio Transformation

328 In order to be able to apply standard statistical methods to composi-
 329 tional data it must be transformed to remove the inherent correlation of
 330 the values. Compositional data analysis proposes special transformations
 331 that change the compositional data values to unconstrained real values. One
 332 such transformation is isometric log-ratio (*ilr*) transformation (as proposed
 333 by [20, 22]):

$$\begin{aligned} z &= (z_1, \dots, z_{D-1}), \\ z_i &= \sqrt{\frac{i}{i+1}} \log \frac{\sqrt[i]{\prod_{j=1}^i x_j}}{x_{i+1}} \text{ for } i = 1, \dots, D-1 \end{aligned} \quad (6)$$

334 where x is the vector that is being transformed and z is the vector that
 335 is created. It should be noted that z is shorter than x by one element.

336 After compositional data vectors are transformed using zero replacement
 337 and *ilr*, any standard statistical tests can be applied.

338 3. Related Work

339 A systematic review of requirements prioritization methods is presented
340 in [23]. The paper focuses on prioritization method comparison and selects
341 eight relevant studies. Two of the studies use CV. These studies are also
342 revealed by the systematic literature review conducted as part of this study.
343 Khan [23] concludes that there is little research on requirements prioritization
344 and studies usually deal with a small number of requirements.

345 The systematic literature review presented in this paper does not reveal
346 any CV result analysis methods that allows to identify prioritization items
347 with equal priority. Thus, this problem is not addressed in any way.

348 4. Methodology

349 This section covers the research questions of this study and the methods
350 used to answer them.

351 4.1. Selection of Research Methods

352 The main purpose of this study is to collect knowledge on the use of CV
353 in order to help software engineers and researchers in adopting it. This will
354 answer RQ 1 and RQ 2.

355 One way of collecting this knowledge is to conduct an empirical study.
356 A survey in a large number of software companies can be used to quantify
357 the level of adoption of CV in industry (similarly to the study by [24]). Case
358 studies can be used to receive qualitative feedback on the use of CV [25].

359 Knowledge on the empirical use of CV can also be obtained from exist-
360 ing studies. This may be done by means of a systematic literature review.
361 Several studies have used CV empirically in industrial as well as in academic
362 settings. Nevertheless, there are no studies that provide an overview of the
363 current state of the practice in this field. Therefore, before continuing with
364 the refinement of CV and conducting new empirical studies (i.e. case study
365 or experiment), a systematic literature review is required.

366 This paper proposes a new method for CV result analysis, called Equality
367 of Cumulative Votes (ECV). (ECV groups prioritization items into groups
368 of items with similar priority.) As will be presented later, the systematic
369 review did not reveal any methods that solve this problem; however, ECV
370 needs to be evaluated and, hence, applied to CV results.

371 There are two options to obtain CV results in order to test ECV. One is
372 to conduct a new empirical study. The second option is to collect CV results
373 from existing studies. The latter approach also has the added benefit to

try to replicate the results from previous studies and if the CV results from other studies are used, a larger amount of data can be obtained with less effort. Moreover, the generalizability of the evaluation is increasing when prioritization results from different sources and domains are used. On the other hand, the main benefit of conducting a separate empirical study is the possibility to control the conditions of CV.

In our study we evaluated ECV by obtaining data from previously conducted studies as found by the systematic literature review. In order to obtain the data, authors of relevant primary studies were contacted.

In short, this study consists of two parts: a systematic literature review of CV and an evaluation of ECV.

4.2. Research Questions

The systematic review should focus on catching studies that empirically use CV. Information about place, time, scale, and domain of the studies should be collected and the results of the review will hopefully aid academic researchers by identifying paths for further investigation of CV. First research question is:

RQ 1. What is the state of practice in empirical studies that use CV?

The level of trust in research results considering CV is determined by the quality of the studies that use CV, hence this study includes an evaluation of the quality of primary studies identified by the systematic review.

Next, a valuable aspect of decision making is the analysis of prioritization results. Thus, the second research question is:

RQ 2. What CV result analysis methods have been presented in papers as identified by RQ 1?

Finally, the evaluation of ECV answers the third research question:

RQ 3. Is ECV capable of identifying prioritization items with equal priority?

5. Systematic Literature Review

This section presents the design of the systematic review. For the results of the execution please see Section 7.1 and 7.2.

Table 2 presents an overview of activities performed during the systematic literature review. The review protocol was developed by one researcher

Table 2: Review activities.

Review phase		Researchers involved
Trial search in databases		A
Develop review protocol		A
Evaluate review protocol		B
Paper search and selection from databases	Search in databases	A
	Search string validation	A
	Selection based on metadata	A and B
	Selection based on full text	A and B
Pilot data extraction (3 papers)		A
Paper selection from the reference lists	Selection based on metadata	A and B
	Selection based on full text	A and B
Data extraction		A and B
Data synthesis		A

407 and evaluated by another researcher. Studies were searched for in two iter-
408 ations. The first search is performed by using databases. The second search
409 is performed using snowball sampling [26]. (Snowball sampling examines the
410 references of primary studies revealed by the first search.) References that
411 are relevant to the review, i.e. they pass the selection criteria, are then added
412 to the set of primary studies.

413 The search for papers was performed by a single researcher. Study se-
414 lection, on the other hand, was performed by two researchers. First, one
415 researcher examined all found studies. Next, another researcher re-examines
416 all studies classified as primary studies in addition to 20 randomly selected
417 excluded studies to ensure the quality of the selection.

418 To ensure the quality of the review, the quality evaluation and data ex-
419 traction is performed independently by two researchers. Inter-rater analysis
420 was performed using Krippendorff’s Alpha statistics. [27, 28].

421 5.1. Data Sources and Search Strategy

422 This systematic literature review is designed based on the guidelines by
423 Kitchenham [29]. First a trial search in electronic databases was conducted.

A – Cumulative voting	E – hundred dollar method
B – 100 dollar method	F – hundred dollar test
C – 100 dollar test	G – hundred point method
D – 100 point method	

424 In order to scale the review to a manageable, yet sufficient size, databases
425 were searched with different search strings. Relevant papers that were found
426 during the trial search were used to extract additional search strings. The
427 trial search revealed that the number of studies that use CV is not very large.
428 Therefore, we decided to include not only software engineering studies but
429 also studies in other research areas, such as forestry or corporate governance.

430 Since CV is frequently used in studies without mentioning this in the
431 abstract, full text search in databases is preferable. Unfortunately not all
432 databases support full text search. Full text search was performed in the
433 IEEE Xplore and Springer Link databases. In ACM Digital Library, In-
434 spec/Compendex, ISI Web of Knowledge, and SCOPUS only metadata was
435 searched. Search strings consist of a Boolean expression: (A or B or C or D or
436 E or F or G), where:

437 Search strings contained only synonyms of CV and they did not limit the
438 research area to software engineering. The search was performed indepen-
439 dently using each of the search strings in each database. All search results
440 were combined and documented using reference management software. The
441 quality of the search strings and the selection of electronic databases were
442 validated against a previously known core set of papers—[3, 30, 10, 31]—
443 checking that all papers from the core set were found by the search.

444 5.2. Study Selection

445 To select relevant papers a set of criteria were designed. The criteria for
446 paper selection are presented in Tables 3 and 4.

447 Papers were selected in two phases: selection based on metadata and
448 selection based on full text.

449 Obviously, the main criterion for inclusion of a paper is that it must
450 present empirical use of CV or present an analysis of the results of using
451 CV. However, there are papers that pass this criterion but are not relevant
452 for this review. CV is frequently used in computer algorithms. There is
453 a significant difference between the way that humans and computers make
454 decisions. Since this review is concerned with human decisions we excluded
455 papers that present CV that is not performed by humans. In addition, only
456 papers that were written in English were selected and duplicate studies were
457 automatically excluded by the citation management software used in this
458 review.

Table 3: Paper search and selection in the databases.

Selection phase	Inclusion criteria	Number of papers selected
Search in databases	published from 2001 until 2011 (databases last accessed Feb. 20, 2011)	256
	contains search strings	
Selection based on metadata	exclude duplicates and tables of contents	177
	written in English	
Selection based on full text	full text is available	127
	study involves empirical use of CV or presents analysis of empirical use of CV	58
	CV is done by humans and not software	25

Table 4: Paper selection from the reference lists of the selected papers.

Selection phase	Inclusion criteria	Number of papers selected
Selection from references	papers included in the reference lists of relevant papers found in databases	467
Selection based on metadata	written in English	462
	reference is already revealed by search in databases	450
Selection based on full text	full text is available	329
	study involves empirical use of CV or presents analysis of empirical use of CV	15
	CV is done by humans and not software	

459 5.3. Quality Evaluation

460 The goal of quality evaluation is to determine the best primary studies
461 according to some measure of quality. Since the number of studies that use
462 CV is not large, quality evaluation was not used as an exclusion criterion.

463 5.3.1. Is the Study Right?

464 Study quality obviously depends on the correctness of the study process
465 including planning, operation, analysis and interpretation of the results. The
466 correctness of the process can be measured by evaluating the description of
467 the study or replicating the study. Thus, to gain the trust of industry prac-
468 titioners and other researchers, the process of the study must be rigorously
469 described. In short, the description must facilitate replication of the study
470 as well as the presentation of limitations and validity threats.

471 5.3.2. Is it the Right Study?

472 Even the most correct and rigorously described study is useless if it does
473 not contribute to the industry or research community. The topic of the
474 research ought to address important goals and issues. The findings of the
475 study should also be significant, i.e. there must be a high probability of the
476 results of the study being true. The significance of the findings depends on
477 how realistic the study is, the correctness of the process and the results of
478 the study, as well as the statistical significance of the findings.

479 **Realism** of a study depends on the context, scale, and subjects of the
480 study. The study should be conducted in a **setting** that is similar or equal
481 to the setting in which the findings of the study are intended to be used.
482 Hence, studies that are conducted in an industrial setting are more valuable.
483 The **subjects** of a study should be similar to the people who are supposed
484 to use the findings of the study. The subjects ought to have appropriate
485 work experience, role in the organization, skills, cultural background, moti-
486 vation, and so forth. The **scale** of a study refers to the size of the study
487 objects. In the case of this systematic review the scale of a study is mea-
488 sured as the number of prioritization items. Study in academia may have a
489 large number of prioritization items. At the same time, an industrial study,
490 with professionals as subjects, may involve a smaller number of prioritization
491 items.

492 Each study may have a different level of realism. Some studies involve
493 industry practitioners in an academic setting to simulate real word practice
494 in a laboratory environment. Other studies may involve academic researchers
495 that execute a real project. For example, researchers may be developing open

496 source software. On the reality scale these studies are somewhere in between
497 the purely academic and industrial studies.

498 The **type** of the research study can be considered as a criterion for the
499 evaluation of study realism. [32] suggest that study designs that are more
500 rigorous (e.g. experiments) are more realistic than observational studies (e.g.
501 case study) due to a higher level of control. On the other hand [33] rate study
502 designs based on other criteria, i.e. how frequently each type of study de-
503 sign is used in an industrial or academic setting. If a study design is used
504 more in an industrial setting, then it is considered more realistic. For in-
505 stance, in software engineering case studies are frequently used in industrial
506 settings, whereas, experiments are usually performed in academia using stu-
507 dents as subjects. Therefore, [33] argue that case studies are more realistic
508 than formal experiments. Obviously the effect of study design on the study
509 realism may be interpreted in different ways. Therefore, we will not use this
510 parameter in our quality evaluation.

511 The statistical significance of the results of a study can be used to evalu-
512 ate the significance of the study findings. This measure will not be used, be-
513 cause the studies that are evaluated belong to very different research areas.
514 Thus, the significance levels of the findings of the studies are not directly
515 comparable. Additionally, sometimes no result is more interesting than a
516 significant result. If study results does not conform to the expectations of
517 researchers, this may reveal important gaps in existing knowledge. Never-
518 theless, the evaluation of the correctness of the study process verifies that
519 the statistical analysis is performed and significance levels are reported.

520 The ultimate goal of research, at least in software engineering, is in many
521 cases industry impact. However, most of the time ideas need to be developed
522 and validated in academia before industry professionals will risk to adopt
523 them. Therefore, academic impact is important as well. Academic impact
524 is usually measured by the number of citations. Academic impact is also
525 measured for particular researchers, using the number of papers she has
526 published and the number of citations of her papers. This measure will
527 not be used in our quality evaluation because it is somewhat biased. The
528 number of citations is likely to be lower for newer papers and the number
529 of papers that a researcher has published gives little information about the
530 actual quality or impact of her research.

531 5.3.3. *Rating of the Studies*

532 The quality evaluation in our review is based on the evaluation of: (i)
533 Study realism. (ii) Study scale. (iii) Availability of raw results of CV. (iv)
534 Quality of the research methodology.

Table 5: Rating of study reality level

Aspect	Contribute to relevance (rating 1)	Do not contribute to relevance (rating 0)
Subjects	Industry professionals	Academia students or teachers, or other
Context	Industrial	Academia

Realism of the studies is rated in three aspects: subjects, setting, and scale. The subjects and setting is rated according to Table 5. The total rating of study realism is determined by summing up the ratings of the two aspects. For instance, if a study is conducted with industry professionals as subjects in an academic context the study will receive rating 1.

In order to rate the scale of a study the number of prioritization items is counted. If a paper presents several prioritization cases only the prioritization with the largest number of the prioritization items is considered. If HCV is used all of the prioritization items on different levels are counted together. However, if an item is present in several groups in the hierarchy it is counted only once.

The availability of raw results of CV is rated separately because it is especially important for our purposes. The data availability rating criteria is given in Table 6. If the results of a study are not available it is not possible to validate the results of the study and, hence, the credibility of the findings is lower. Ideally the data collected in the study should be presented directly in the paper. An alternative may be to make the data freely available online and reference the online source.

The quality of the research methodology of a paper is rated according to checklist presented in Appendix C. The checklist is based on guidelines for presenting research studies as presented in [34, 35] and the guidelines for quality evaluation of research studies presented in [33, 29]. Evaluation is done with regard to the rigor of the description and correctness of the research process and reasoning. Checklist items represent issues that research studies should implement and present in research paper. The checklist also contains item descriptions or questions that are used to evaluate the quality. Each item in the checklist is rated according to criteria presented in Table 7. The final rating of correctness of the research process of a study is computed by summing up the ratings assigned to all items in the checklist.

Study rating criteria was validated during a trial data extraction. Two researchers each rated three randomly selected papers. Afterwards, differences in ratings were discussed and study rating criteria were updated to avoid differences in interpretation.

Table 6: Research data availability rating

Rating	Study rating criteria
0	CV results was not provided in the paper and we was unable to obtain the results from the authors.
1	CV results are not provided in the paper but the data was obtained from the authors. Part of the data is lost or corrupted.
2	CV results are not provided in the paper but all the data was obtained from the authors.
3	All CV results are included in the paper or reference is given to online source where all the data can be accessed.

Table 7: Rating of correctness of research process

Rating	Study rating criteria
0	No description provided.
1	Only basic information is provided about the checklist item. Or significant validity threats exist with regard to this item.
2	Description is sufficient. Some minor questions are left unanswered. Validity threats may exist but they are not likely to affect the results of the study.
3	Description is rigorous and clear. Questions presented in quality evaluation checklist in Appendix C are answered. Decisions of the study are well justified, alternatives are discussed. No unhandled validity threats can be identified.

568 As a result of the rating each study was assigned four rating values in
569 an ordinal scale. In order for us to perform a more advanced analysis of
570 the quality evaluation results these ratings were then converted into ratio
571 scale ranks. For each study, the number of studies that have received lower
572 ratings is counted. The resulting number is the rank of the study; thereby,
573 the quality of a study is expressed as four rank values.

574 An example of rating values is shown in Table 8. Table 9 shows ranking
575 values computed for the studies in Table 8. We can observe that study
576 realism level rating for ST3 is 0. There are no studies that have a lower
577 study realism. Therefore, realism ranking for ST3 is 0. ST1 on the other
578 hand has the highest realism rating. Since ST1 has higher reality level than
579 both ST2 and ST3 it is assigned reality level rank 2.

Table 8: Example of rating values

Study	Realism	Research data availability	Correctness of research process	Number of prioritization items
ST1	2	0	15	6
ST2	1	3	20	69
ST3	0	3	10	6

Table 9: Example of ranking values

Study	Reality level	Research data availability	Correctness of research process	Number of prioritization items
ST1	2	0	1	0
ST2	1	1	2	2
ST3	0	1	0	0

5.4. Data Extraction

The goal of the data extraction is to understand how and why CV is used and how CV results are analyzed in research studies. Ultimately, this will allow us to answer the first and second research questions in our study.

Data extraction was documented with the help of spreadsheet software. Extracted data items are available from [36].

6. Equality of Cumulative Votes

In the last section we described the execution of the systematic literature review. In order to perform a more thorough analysis later we here present the design of ECV before presenting the results of the systematic literature review. For the results of the evaluation of ECV please see Section 7.3 (ECV is implemented in the *R* programming language [37] and the code can be found at [38].)

In CV stakeholders may assign similar or equal values to several prioritization items. As a result the difference between the items is small. The variation in priorities is caused not only by the difference between prioritization items but also by human error and lack of information for decision making. For instance, people tend to simplify the task of prioritization by assigning rounded values to items or giving equal values to several items [39].

During prioritization it may be beneficial to know which items are equal. A common example is software release planning where requirements are distributed among several product releases. If two or more requirements are considered equal they can be freely interchanged between the releases, and other criteria, such as cost or effort, may be used to used as sole indicators for planning that particular release.

6.1. Testing Equality of Two Items

There are two ways to determine which prioritization items have similar priority. One approach is to find items that are different and consider other items as equal. Another approach is to find items that are equal.

609 The first approach uses statistical tests to evaluate differences between
 610 two population means in order to determine that two items are different.
 611 Populations in this case consist of priorities assigned by all stakeholders to a
 612 particular prioritization item. The number of stakeholders that perform the
 613 prioritization is frequently small. Hence, the size of the sample is very often
 614 too small for statistical tests to detect a significant difference and the tests,
 615 thus, identify too many equal items to make any useful conclusions.

616 ECV, in contrast, uses the second approach. It finds items that are
 617 similar and the rest of the items are considered different. This method tests
 618 the probability of the difference between the means of two items being smaller
 619 than the given value. In short, ECV tests the probability of the means of two
 620 prioritization items differing by less than 25%. If the probability is higher
 621 than 70% the items are considered equal.

622 The input to ECV is an $n \times p$ matrix A that contains the raw results of
 623 the prioritization. The columns of the matrix represent prioritization items
 624 while rows represent stakeholders. ECV performs the following operations
 625 for the priorities of each two prioritization items:

- 626 1. Replace zeroes in CV results.
- 627 2. Transform the data using *ilr* transformation.
- 628 3. Determine distribution function using kernel density estimation.
- 629 4. Use the distribution function to find the probability that the difference
 630 between two prioritization items is smaller than 25%.
- 631 5. Form groups of equal prioritization items.

Since CV results are compositional data, zeroes in A must be replaced
 with other values. This is done using the multiplicative replacement strategy
 which is described in Section 2.4.1. Next, two columns are extracted from
 matrix A to create the new matrix B :

$$B = [a_{*,k} a_{*,l}] \quad (7)$$

632 where a is an element of matrix A , and k and l are the columns that
 633 represent items that are tested for equality.

634 The *ilr* transformation is then applied to each row of the matrix B and
 635 the new vector C is obtained. The equation for calculating elements of C
 636 using *ilr* transformation is:

$$c_i = ilr(b_{i1}, b_{i2}) = \sqrt{0.5} \log(b_{i1}/b_{i2}) \quad (8)$$

637 where c_i is the i^{th} element of C and b_{i1} and b_{i2} are the first and second
 638 elements in the i^{th} row of B . Each value c_i represents a ratio between k

639 and l . The mean of the values of C can be interpreted as an average ratio
640 between the items that expresses the difference between the items.

641 After the data is transformed into log-ratios statistical test can be ap-
642 plied. The purpose of the test is to determine what the probability is of the
643 relative difference between two prioritization items k and l being less than
644 25%. This means determining the probability of the ratio k/l between the
645 items k and l as being in the range of $\frac{3}{4}$ to $\frac{4}{3}$. Or in terms of log-ratios
646 it means determining the probability of $ilr(k, l)$ being between $ilr(3, 4)$ and
647 $ilr(4, 3)$. Hence, the objective of the test is to determine the probability of
648 the sample mean (i.e. mean value of C) laying between the two values.

649 The probability that the mean takes a particular value can be expressed
650 in form of a cumulative distribution function. The probability of the mean
651 being between two values a and b (where a is smaller than b) can be deter-
652 mined by subtracting the probability of the mean being smaller than a from
653 probability of the mean being smaller than b .

654 However, CV result data may or may not be normally distributed. If the
655 data is normally distributed a Student's t distribution function can be used.

656 Otherwise a non-parametric estimation of the distribution function is
657 needed. In our case, the CV result data obtained from the primary stud-
658 ies identified by the systematic review, were tested for normality using the
659 Anderson-Darling test. The tests we performed indicated, quite strongly,
660 that in most of the prioritization cases the data is not normally distributed.
661 Hence, our recommendation is that, in general, a non-parametric approach
662 should be used to determine the probability density function, and one such,
663 common, approach would be to use the kernel density estimation. (In our
664 implementation of ECV in the R programming language, kernel density es-
665 timation is performed using the package *ks*.)

To determine the probability of \bar{x} being between a and b the following
equation is used:

$$p = P(b) - P(a) \quad (9)$$

666 where P is the cumulative distribution function obtained by applying
667 kernel density estimation on ilr -transformed priority values denoted by vec-
668 tor C . Variable a is equal to $ilr(3, 4)$ and b is equal to $ilr(4, 3)$. (A graphical
669 interpretation of Equation (9) is presented in Figure 5.) The area that is
670 denoted by letter p represents the probability computed by the equation.

671 After both prioritization items are tested for equality it may be conve-
672 nient to display the equality of different items in the form of a table. Please
673 see Table 10 for an example.

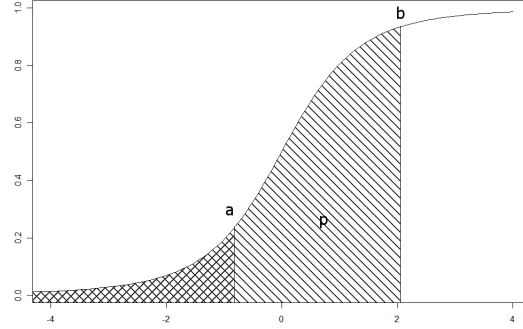

Figure 5: Cumulative distribution function of the ratio k/l between the items k and l (area p denotes probability that k/l is between $\frac{3}{4}$ and $\frac{4}{3}$.)

Table 10: Example of equality table

prioritization items	i1	i2	i3	i4
i1	equal	equal	-	equal
i2	equal	equal	-	-
i3	-	-	equal	-
i4	equal	-	-	equal

6.2. Grouping Prioritization Items

When equal items are determined they must be divided into groups of equal items. Division must be performed in such a way that each two items in a group are equal. The test for equality of the items described in Section 6.1 is not transitive. Hence, if prioritization item A is equal to B and B is equal to C then it does not automatically imply that A is equal to C . Therefore, there may be several ways to group the equal items. The two possible division criteria that we have considered in this study are:

1. Maximize the number of items that have a group.
2. Maximize the number of items in each group.

7. Results

This section presents the results of this study including the systematic literature review and the application of ECV on industry and academic data. Data extracted from primary studies and the results of the quality evaluation are available in [36].

689 *7.1. State of Practice in Empirical Studies that use CV or Analyse the Re-*
690 *sults of CV (RQ 1)*

691 The study search resulted in 634 unique studies. The search in databases
692 revealed 180 papers, while an additional 454 papers were discovered us-
693 ing snowball sampling. The study selection resulted in 40 primary studies.
694 Hence, 94% of studies were excluded by the selection criteria. Snowball
695 sampling revealed 15 or 36% out of all primary studies. The study selection
696 criteria and the number of papers excluded by each criterion are shown in
697 Tables 3 and 4. In total 163 of 634 studies were excluded because full text
698 was not available.

699 The review process was facilitated by the reference management software
700 Mendeley. All results of the study selection are available online and can be
701 obtained by contacting the authors of this paper. For each study we specify
702 keywords and databases that were used to find the study. If a study has
703 been excluded, the exclusion criteria are provided.

704 The number of papers revealed by each search string and database is
705 presented in Table 11. It should be noted that several papers were found
706 by more than one search string or in more than one database. Table 11
707 shows that the search string ‘cumulative voting’ was the most frequently
708 used in research community to denote CV. Therefore, researchers should use
709 or reference this term when talking about CV.

710 To perform snowball sampling we examined the references of primary
711 studies that were found during the database search. References were used
712 to search for the papers in the Google and Google Scholar search engines.
713 Studies that were found in the search and passed the study selection criteria
714 were added to the set of primary studies.

715 After the primary studies were selected, data extraction and quality eval-
716 uation was performed by two researchers. One researcher examined all stud-
717 ies while the second researcher did quality evaluation and data extraction for
718 10% of the studies. The studies were randomly selected. Inter-rater agree-
719 ment were calculated by means of Krippendorff’s alpha coefficient. Agree-
720 ment for data extraction results is 0,86 and agreement for the quality evalu-
721 ation is 0,73. According to Krippendorff [28] it is common to require agree-
722 ment above 0,8 and the lowest acceptable agreement is 0,667. Therefore,
723 we conclude that agreement calculated for this study is sufficient. Ratings
724 of the study setting, correctness, research data availability, and number of
725 prioritization items are presented in Figure 6.

726 Table 12 shows the studies with the highest quality according to our cri-
727 teria. These studies show a high level of rigor in a realistic setting. Moreover,

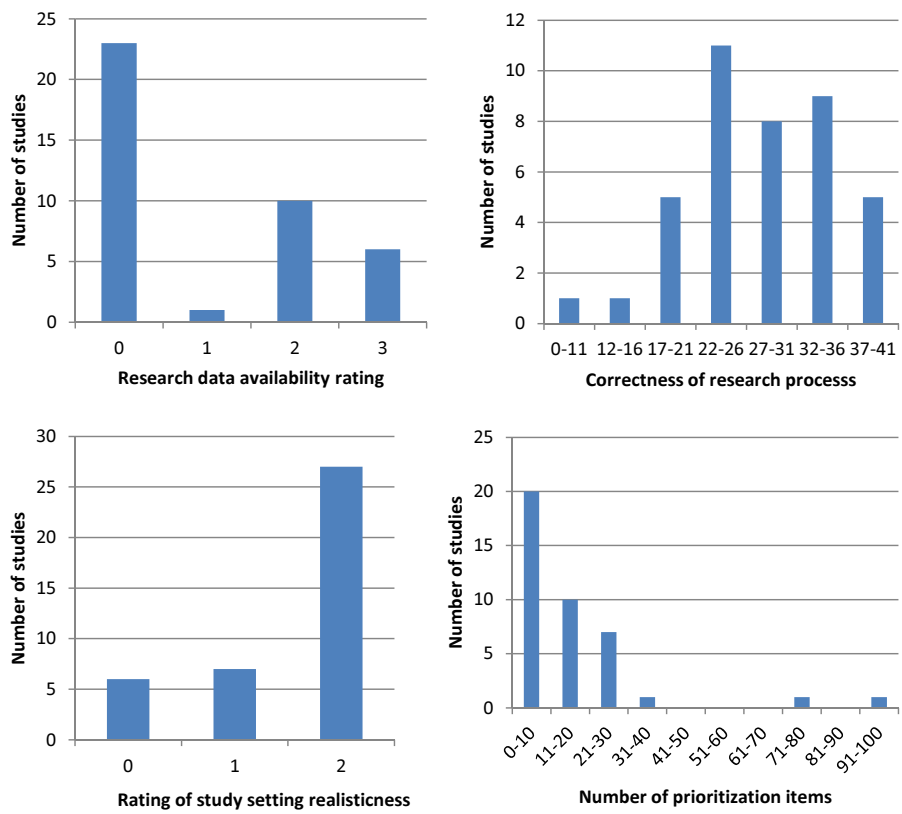

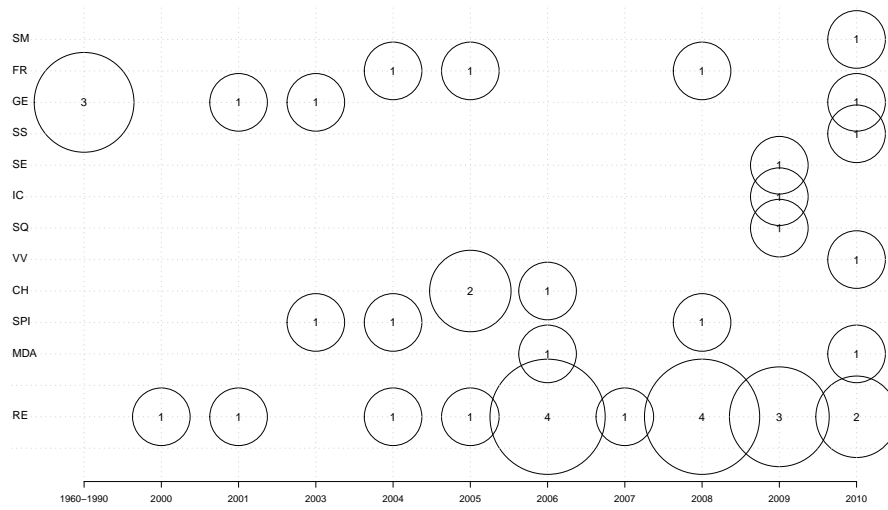

Figure 6: Study quality ratings

MDA - model driven software development	FR - forestry
CH - change impact analysis in software engineering	GE - government elections
RE - requirements engineering and software release planning	SS - software security
IC - intellectual capital in software company	SQ - software quality
SPI - software process improvement	SM - software metrics
VV - software verification and validation	SE - software engineering in general

728 authors of the studies manifest confidence by providing raw data for further
729 use and evaluation.

730 Figure 7 shows a bubble chart of the distribution of studies over research
731 areas and time. The figure shows that CV was first applied some time
732 ago in research of government elections. Nowadays, though, CV has been
733 adopted in a wide range of software engineering areas. Most frequently in
734 requirements engineering and software release planning. Eight studies use
735 CV as a research method while the remaining 32 studies use it as industry
736 practice.

737

738 7.2. CV Result Analysis Methods Identified by RQ 1 (RQ 2)

739 The papers identified in the systematic review use various CV result
740 analysis methods. The main goals for CV result analysis are presented in
741 Table 13 and a summary of methods used in the primary studies can be
742 found in Appendix B.

743 In order to reflect prioritization results many studies use charts or tables.
744 These charts and tables show the average priority of each prioritization item
745 that is computed from priorities assigned by all stakeholders. In [47] a table
746 of five items with highest total priority is presented. [48] shows tables with
747 minimum, maximum, median, mean, and standard deviation of priorities
748 assigned by different stakeholders to a particular prioritization item. Finally,

Table 12: Top ranked studies.

	Correctness of research process	Research data availability	Study setting	Number of prioritization items
Barney et al. [40]	36	2	2	17
Berander and Svahnberg [17]	41	2	0	29
Barney et al. [41]	40	2	2	5
Barney and Wohlin [8]	31	2	2	27
Barney et al. [42]	34	2	2	14
Laukkanen et al. [43]	22	3	2	30
Hu [44]	34	2	1	14
Feldt et al. [45]	24	3	2	8
Regnell et al. [31]	21	3	2	91
Svahnberg et al. [46]	34	1	1	7

in [49, 48] error bars are added to the chart of final priorities (denoting the standard deviation of priorities).

In a few cases final priorities are presented in the form of ranks and CV results are degraded from ratio to ordinal scale. This is done when the interest lies only in the order of final priorities.

Several papers are interested in the difference between priorities from different prioritization perspectives (e.g. current and ideal situation) or stakeholder groups (e.g. software developers and management). Pearson or Spearman correlation coefficients are commonly used to determine what the level of similarity between all priorities from two perspectives is. Whereas, Wilcoxon, Kruskal Wallis, Nemenyi-Damico-Wolfe-Dunn tests and the χ^2 statistic are used to detect if there is a significant difference in the value of one prioritization item from two or more perspectives. In addition, PCA is used to detect if there are distinct groups of stakeholders with common priorities [10, 7, 50].

In some cases, a stakeholder may assign equal priority to several prioritization items or leave several items unrated, e.g. the stakeholder may not have carefully considered all prioritization items. Hence, the difference between the items may have been unnoticed.

In [4] the scalability of prioritization is measured using two charts. The first chart shows the average percentages of items given a non-zero value. The second chart shows average percentages of divergence of values. If a stakeholder assigns equal priorities to many prioritization items the divergence of values is low. Unfortunately it is unclear from [4] how the average percentage of divergence is calculated.

In [51] distribution, disagreement, and satisfaction charts are presented. The distribution chart shows how the final value of a prioritization item is constructed from priorities assigned by different stakeholders. This chart

Table 13: Goals for CV result analysis.

Purpose of the method	Name
Show the final priority of each prioritization item. Stakeholder priorities are combined into one value.	Chart or table of final priorities
Difference between priorities assigned by different perspectives (status quo, ideal situation) or different stakeholder groups (developers, management) [10]	Biplot
detect stakeholder groups with similar priorities [10]	Biplot
show the relative number of issues that have received high, medium, or low priority [10]	Ternary plot
detect stakeholder groups with common priorities [10]	PCA
how the final value of prioritization item is constructed from priorities assigned by different stakeholder. This chart shows how much each stakeholder has contributed to the final value of prioritization item [51]	Distribution chart
the level of agreement between different stakeholders on value of particular prioritization item [51]	Disagreement chart
satisfaction of a stakeholder with the prioritization results by the calculating correlation between the final priorities and priorities assigned by a stakeholder [51]	Satisfaction chart
percentage of the divergence of the priorities assigned by a stakeholder [4]	average percentage of divergence
average percentage of items given a non-zero value [4]	
detect equal prioritization items (presented in this paper)	ECV

shows how much each stakeholder has contributed to the final value of a prioritization item. The disagreement chart shows the level of agreement between different stakeholders on the value of a particular prioritization item. The satisfaction chart shows stakeholder satisfaction with prioritization results by calculating the correlation between final priorities and priorities assigned by a stakeholder.

The use of biplots and ternary plots are proposed in [10]. A biplot shows final priorities and stakeholder viewpoints in a two dimensional plane while a ternary plot shows prioritization items inside a triangle. Ternary plots show how many low, medium or high priorities are assigned to a prioritization item. The corners of the triangle represent high, medium, and low priority, e.g. if a prioritization item has received mostly high priority values then it is shown closer to the high priority corner.

7.2.1. Problems with Compositional Data Analysis in Primary Studies

A few primary studies, as revealed by the systematic review, have problems with the analysis of compositional data.

In [50, 7] standard PCA is performed without applying log-ratio transformations to compositional data. According to [52], this is likely to be inadequate and in [53], a more appropriate method for performing PCA of

Table 14: Identified groups of equal items.

Paper identifier & Description	Type of CV	Pairs of equal items	Groups of equal items
Barney et al. [41] Perceived priorities of software product investments in an ideal situation	comp. HCV	(A2, B4) (B4, B5) (B4, C1) (B5, B15) (B6, B7) (B7, B8) (B14, B15) (B14, B18) (B17, B18)	(A2, B4) (B4, C1) (B5, B15) (B6, B7) (B14, B15) (B17, B18)

795 compositional data is shown.

796 The normality of compositional data is defined in [54]. It is stated that
 797 compositional data must first be transformed using isometric log-ratio trans-
 798 formation before the tests for normality can be applied. [47] violates this re-
 799 quirement by applying the Shapiro-Wilk test for normality to untransformed
 800 compositional data.

801 The Kruskal-Wallis test is used in [47] to analyse compositional data.
 802 The test is used to evaluate the difference between three organization levels.
 803 The Kruskal-Wallis test assumes that variables within each sample are in-
 804 dependent [55]. However, values within compositional data vectors are not
 805 independent (as described in Section 2.4). Hence, we claim the Kruskal-
 806 Wallis test to be somewhat misused in [47].

807 7.3. Identifying Prioritization Items with Equal Priority Using ECV (RQ 3).

808 This section presents the results of applying ECV to the industrial and
 809 academic CV result data as found through the systematic literature review.

810 Six primary studies included the raw prioritization results in the paper itself
811 or referenced online sources where the data was available. To collect the data
812 from the remaining 34 papers, the author(s) of all papers were contacted.

813 First, the email addresses provided in the papers were used. If no answer
814 was received authors were searched for using Google, Facebook and LinkedIn.
815 Authors from 11 papers provided us with data to be used in the evaluation
816 of ECV. However, due to confidentiality reasons we can not publish this data
817 directly and instead urge interested parties to contact the authors directly.

818 In short, ECV was applied to 27 CV prioritization cases from 14 studies.
819 In the cases of HCV, ECV was applied two times to the same data to test
820 both compensated and uncompensated priorities. Equal items were detected
821 in three prioritization cases. A summary of the results of is presented in
822 Table 14.

823 In [46] a prioritization of requirement understandability criteria is pre-
824 sented. ECV shows that from the viewpoint of academia researchers, devel-
825 opment have the same importance as product planning (i.e. making strategic
826 product planning decisions: release planning, choosing which requirements
827 to dismiss).

828 A prioritization of software requirements for an academic course man-
829 agement system is presented in [17]. ECV detected that two features—
830 Assignment Submission and Assignment Feedback—have the same priority.

831 In [41] software product investments are prioritized with HCV. The re-
832 sults of ECV was different for uncompensated and compensated HCV results.
833 When compensated HCV was used ECV detected equal items that belong to
834 different high level prioritization groups (*A*, *B* and *C*). Whereas, in case of
835 uncompensated HCV all equal items belong to one high level prioritization
836 group (group *B*).

837 8. Discussion and Conclusions

838 This section discusses the results of the systematic review and evaluation
839 of ECV conducted as part of this study.

840 CV has been applied in various areas, but most frequently in requirements
841 prioritization and release planning, and quite often also as part of research
842 methodologies. A large part of the studies have been conducted in Sweden,
843 at Ericsson AB. One can see a slight increase in the interest in CV. During
844 the last five years there have been more studies that use CV than between,
845 say, year 2000–2005.

846 Overall, studies that use CV or analyse the results of CV have high qual-
847 ity in terms of correctness of research process and study realism. However,

848 very few studies present prioritization of more than 30 items and the avail-
849 ability of research data is somewhat limited. In our particular case we were
850 able to obtain data from 43% of studies.

851 *8.1. Implications for Practitioners*

852 The results of this study provide decision support for industry practi-
853 tioners. We believe that a collection of state of the practice studies help
854 the adoption of CV prioritization method. (Top studies are summarized in
855 Table 12.) In addition, a set of CV analysis methods enables comprehensive
856 understanding of the prioritization results. (The analysis methods are pre-
857 sented in Table 13.) One of the most common goals of CV analysis are to
858 display of the prioritization results and, thus, to show the difference between
859 several prioritization perspectives.

860 Additionally, we present ECV—a novel method for CV analysis. Priori-
861 tization often results in the assignment of similar priorities to several prior-
862 itization items. ECV identifies prioritization items with similar priority and
863 tests whether these items can be considered equal. In this case, ECV can
864 be used in software release planning. For example, let us suppose that a set
865 of software requirements are prioritized with regard to the implementation
866 cost. First of all, ECV can then detect items with equal cost. Second, the
867 equal items can be freely swapped between the releases. Finally, the deci-
868 sion to allocate a requirement to a particular release can be made based on
869 another criteria, such as risk or business value.

870 ECV has been successfully applied on a considerable amount of CV data
871 and, additionally, has also detected equal items in different groups of HCV
872 hierarchies.

873 *8.2. Implications for Academia*

874 In the systematic review 36% of papers were revealed by the snowball
875 sampling. That is a considerable amount. Several studies do not mention
876 the name of the prioritization method (i.e. cumulative voting or hundred
877 dollar test). Others are not available through selected databases because
878 they are conference publications or theses. It shows, in our opinion, that
879 snowball sampling ought to be used in all systematic literature reviews.

880 CV results are a special type of data—compositional data. Standard
881 statistical analysis methods that assume the independence of the samples
882 cannot be applied to CV results. In [56] methods for the analysis of com-
883 positional data have been presented. The systematic review conducted as a
884 part of this study revealed that 22 studies analyse the results of CV. Yet,
885 only one study uses compositional data analysis methods, i.e. [10].

886 The small use of compositional data analysis is really not surprising,
887 because literature describing CV does not state that the results are com-
888 positional data. Standard statistical analysis methods may produce useful
889 results for compositional data. However, there are cases when they are mis-
890 leading or even faulty. Section 7.2.1 contains evidence of inappropriate use
891 of statistical methods by several papers.

892 This study has collected a set of compositional data analysis methods for
893 CV analysis (see Table 13). We believe that this could help researchers to
894 improve the analysis of CV results with appropriate methods.

895 Since CV is associated with compositional data, it might be tempting to
896 choose another requirements prioritization method. However, it would not
897 solve the problem, because any ratio scale prioritization, for instance AHP,
898 contains compositional data.

899 The principal implications for the academia are the following:

- 900 1. All systematic literature reviews should include snowball sampling.
- 901 2. Researchers can improve their statistical analysis of CV results using
902 compositional data analysis methods collected and developed by this
903 study.
- 904 3. When CV or any other ratio scale prioritization method is taught,
905 compositional data analysis should also be presented as part of the
906 solution.

907 8.3. *Validity Threats*

908 The validity of the systematic review is limited by the chosen databases,
909 the design of the review, and human judgement in study selection and data
910 extraction.

911 To mitigate the threats we use the most popular databases in the field
912 of software engineering. In the beginning of the systematic review a re-
913 view protocol was developed, peer-reviewed, and revised. Search strategy
914 was validated against a set of previously known papers obtained from other
915 researchers. One of many terms used to name cumulative voting is ‘\$100
916 method’. We were not able to search for this term because non of the cho-
917 sen databases support search for special characters like ‘\$’ and the search
918 string ‘100 method’ yields hundreds of thousands of results. To increase
919 the likelihood discovering relevant studies snowball sampling was extensively
920 performed.

921 To increase the validity of study selection, all included studies and 20
922 randomly selected excluded studies were examined by two researchers. There
923 were no disagreement on the inclusion/exclusion of the studies.

924 The large number of studies identified by the snowball sampling (15 out
925 of 40 studies) may be caused by faulty design or execution of the search
926 in the databases. There are several reasons why the studies revealed by
927 snowball sampling are not revealed by the search in databases. Reason for
928 each study is given in Table Appendix A.2. Based on these reasons we argue
929 that snowball sampling does not indicate any problems with the design of
930 the search in the databases.

931 Four studies are not found because they are not available through databases
932 used in this systematic review. Out of them one is master thesis, two are
933 conference publications and one is a publication in the area of forestry. Seven
934 studies do not mention the name of the prioritization method (i.e. hundred
935 dollar method or cumulative voting). Only phrases like "distribution of a
936 predefined amount of fictitious money (\$100,000) over the items to be prior-
937 itized" or "1000 points" allowed us to identify that CV is used. One paper
938 used previously unknown name for CV - 100-point technique.

939 The quality of the data extraction and quality evaluation was validated
940 using inter-rater agreement analysis. In our case, 10% of the studies were
941 rated by two researchers and Krippendorff's alpha was calculated. The agree-
942 ment for the data extraction results was 0.86 and the agreement for the
943 quality evaluation was 0.73 (indicating a credible level of quality).

944 The failure to obtain raw results of several CV studies may be due to
945 several reasons, e.g. the authors of the primary studies might be unwilling
946 to communicate the data because of lack of motivation or spare time. In
947 our case we found that we were able to minimize this threat by searching for
948 the researchers through various channels, e.g. Google search, LinkedIn and
949 Facebook.

950 There are two main validity threats with ECV. First, ECV may not
951 detect prioritization items with equal priority. Second, ECV may produce a
952 false positive result. There may be a real difference between items that ECV
953 claims as being equal.

954 To mitigate the first threat ECV was applied on artificially created test
955 data with and without items with similar priority. ECV worked correctly in
956 both cases.

957 To mitigate the second threat we visually inspected the results of the ap-
958 plication of ECV on the real world data. We concluded that items identified
959 by ECV can be considered equal.

960 CV results used in the evaluation of ECV were tested for normality. The
961 tests indicated that CV results are not normally distributed. Therefore, the
962 design of ECV was based on a non-parametric statistical test.

963 8.4. *Future Research*

964 There are very few studies that apply CV on prioritization sets of more
965 than 30 items. However, in requirements engineering, industry practitioners
966 need to prioritize much larger numbers of software requirements. Therefore,
967 the state of art could benefit from the application CV and HCV to large
968 prioritization sets.

969 The proposed method, ECV, has now been evaluated on existing research
970 data. To further evaluate the ECV, it could be applied in direct industry
971 practice and in prioritization cases with a larger number of prioritization
972 items. Additionally, compositional data analysis methods, as the ones iden-
973 tified by this paper, should be tried with other prioritization methods that
974 produce ratio scale results.

975 8.5. *Conclusions*

976 CV prioritization results are special type of data – compositional data.
977 Any analysis of CV results must take into account the compositional nature
978 of the CV results.

979 This study presents a systematic literature review of the empirical use
980 of CV. CV has been applied in various areas, but most frequently in re-
981 quirements prioritization and release planning. The review has resulted in
982 a collection of state of the practice studies and CV result analysis methods.
983 We believe that it can help the adoption of CV prioritization method.

984 Snowball sampling is performed as a part of the review. Since it revealed
985 36% out of all primary studies, we believe that in future snowball sampling
986 should be used in all systematic reviews.

987 Additionally, we present ECV—a novel method for CV analysis. As
988 suggested by our evaluation, ECV is able to detect prioritization items with
989 equal priority (i.e. items that have insignificant difference in priority). The
990 evaluation of ECV is based on the data obtained from the authors of the
991 primary studies.

1188 Appendix A. Primary Studies

1189 Appendix A.1. Primary studies found during search in databases

	Title	Reference
	Prioritizing Countermeasures through the Countermeasure Method for Software Security (CM-Sec)	Baca and Petersen [57]
	The Relative Importance of Aspects of Intellectual Capital for Software Companies	Barney et al. [40]
	Software Product Quality: Ensuring a Common Goal	Barney and Wohlin [8]
	Balancing software product investments	Barney et al. [41]
	Hierarchical Cumulative Voting (HCV) prioritization of requirements in hierarchies	Berander and Jonsson [4]
	A goal question metric based approach for efficient measurement framework definition	Berander and Jönsson [30]
	Evaluating two ways of calculating priorities in requirements hierarchies - An experiment on hierarchical cumulative voting	Berander and Svahnberg [17]
	Election systems and voter turnout: Experiments in the United States	Bowler [58]
	A Low Information Theory of Ballot Position Effect	Brockington [59]
	Prioritization of Issues and Requirements by Cumulative Voting: A Compositional Data Analysis Framework	Chatzipetrou et al. [10]
	A comparison of cumulative voting and generalized plurality voting	Cooper and Zillante [60]
	Challenges with Software Verification and Validation Activities in the Space Industry	Feldt et al. [45]
	Investigating Impact of Business Risk on Requirements Selection Decisions	Fogelström et al. [61]
1190	Choosing the Right Prioritization Method	Hatton [62]
	Early prioritization of goals	Hatton [63]
	Rigorous Support for Flexible Planning of Product Releases - A Stakeholder-Centric Approach and Its Initial Evaluation	Heikkilä et al. [64]
	Voting methods in strategic forest planning - Experiences from Metsähallitus	Hiltunen et al. [13]
	Empirical extension of a classification framework for addressing consistency in model based development	Kuzniarz [48]
	Evaluation of the multicriteria approval method for timber-harvesting group decision support	Laukkanen et al. [43]
	A practitioner's guide to light weight software process assessment and improvement planning	Pettersson et al. [7]
	An Empirical Study on Views of Importance of Change Impact Analysis Issues	Rovegard et al. [49]
	An Industrial Case Study on the Choice Between Language Customization Mechanisms	Staron and Wohlin [65]
	Perspectives on Requirements Understandability – For Whom Does the Teacher's Bell Toll?	Svahnberg et al. [46]
	A Study on the Importance of Order in Requirements Prioritization	Svahnberg and Karasira [16]
	A structured goal based measurement framework enabling traceability and prioritization	Touseef and Gancel [66]

1191 *Appendix A.2. Primary studies revealed by snowball sampling*

Reference	Title	Reason why the paper is not revealed by the search in databases
Ahl [3]	An experimental comparison of five prioritization methods	Selected databases does not contain the paper, master thesis at BTH
Barney et al. [42]	A product management challenge: Creating software product value through requirements selection	Prioritization method name not mentioned, phrase "1000 points" used instead.
Berander and Wohlin [67]	Differences in views between development roles in software process improvement-a quantitative comparison	Prioritization method name not mentioned, phrase "100 points" used instead.
Berander [68]	Using students as subjects in requirements prioritization	Unknown CV name: 100-point technique
Berander and Wohlin [69]	Identification of Key Factors in Software Process Management-A Case Study	Prioritization method name not mentioned, phrase "100 points" used instead.
Cole et al. [70]	Cumulative Voting in a Municipal Election: A Note on Voter Reactions and Electoral Consequences	Study published before year 2001.
Hu [44]	Adding value to software requirements: An empirical study in the chinese software industry	Prioritization method name not mentioned, phrase "1000 points" used instead.
Jönsson and Wohlin [9]	A study on prioritization of impact analysis issues: A comparison between perspectives	Selected databases does not contain the paper.
Jönsson and Wohlin [47]	Understanding impact analysis: An empirical study to capture knowledge on different organisational levels	Selected databases does not contain the paper.
Kuklinski [71]	Cumulative and Plurality Voting: An Analysis of Illinois' Unique Electoral System	Study published before year 2001.
Laukkanen et al. [72]	Applying voting theory in participatory decision support for sustainable timber harvesting	Selected databases does not contain the paper.
Regnell et al. [31]	An industrial case study on distributed prioritization in market-driven requirements engineering for packaged software	Prioritization method name not mentioned: "distribution of a predefined amount of fictitious money (\$100,000) over the items to be prioritized."
Regnell et al. [51]	Visualization of Agreement and Satisfaction in Distributed Prioritization of Market Requirements	Prioritization method name not mentioned: "distribution of a predefined amount of fictitious money (\$100,000) over the items to be prioritized."
Sawyer and MacRae [73]	Game theory and cumulative voting in Illinois: 1902-1954	Study published before year 2001.
Wohlin and Aurum [50]	Criteria for selecting software requirements to create product value: An industrial empirical study	Prioritization method name not mentioned: "The subjects had 1000 points to spend among the 13 criteria."

Appendix C. Quality Evaluation Checklist

	Item	Question or Description of the Item	Rating
1.	Background, introduction	Introduce research area	
2.	Problem statement, purpose	What is the problem[35]? Where does it occur [35]? Who has observed it [35]? Why is it important to be solved [35]?	
3.	Context, independent variables (aka. environment, setting)	Study location, time constraints, application domain, organization, tools, market, process (e.g. software development methodology), size of project, product that is being developed	
4.	Related work	Other existing work, alternative technologies, solutions, and studies	
5.	Goals and Hypotheses	Null hypothesis and one or more alternative hypotheses for each goal	
6.	Research questions		
7.	Design, Research methods		
7.1.	Design	Description of each step of the study	
7.2.	Control group	If there is a control group, are participants similar to the treatment group participants in terms of variables that may affect study outcomes[29]?	
7.3.	Randomization	Random selection of participants and objects Random assignment of treatment and objects to participants Random order of treatments in case of paired design. If each participant is assigned two treatments A and B, then part of participants perform A first and the other part start with B	
7.4.	Blocking	Group participants of the study into homogeneous groups called blocks (e.g. students in one course, database developers in one company) and implement the study design within each block independently. The idea is that variability of independent variables (e.g. experience and knowledge of subjects) is smaller within a group. That helps measuring changes in dependent variables [32].	
7.5.	Balancing	Equal number of subjects should be assigned to each treatment [32].	
7.6.	Blinding	Automated assignment of treatments to subjects [32] Automated distribution of study materials to subjects [32] Persons who grade the task results should not know which treatment was used [32] Analyst should not know which treatment group is which [32] Automated data collection from subjects [32]	
8.	Subjects (participants)		
8.1.	Population		
8.2.	Sampling	How sampling is performed? What subjects are included and excluded? [29] What is the type of the sampling (e.g. convenience, random)? Is the sample(selected participants) representative of the population?	
8.3.	"Drop outs" and response rate	Are reasons given for refusal to participate[29]?	
8.4.	Subject motivation	E.g. material benefits, course credits for students, etc.	
9.	Objects	E.g. documents and other artefacts	
10.	Measures, Data collection procedures	Who, when, and how does the measurements [29]? How is the measurement supported? Is it automated [29]? Are the measures used in the study the most relevant ones for answering the research questions [29]?	
11.	Analysis procedure		
11.1.	Data description	Do the numbers add up across different tables and subgroups [29]?	
11.2.	Data types (continuous, ordinal, categorical)		
11.3.	Scoring systems		
11.4.	Data set reduction, outliers		
11.5.	Statistical methods	Are the assumptions of statistical methods met? What statistical programs are used?	
11.6.	Statistical significance	If statistical tests are used to determine differences, is the actual p value given [29]? If the study is concerned with differences among groups, are confidence limits given describing the magnitude of any observed differences [29]?	
12.	Validity threats	Threats, implications of the threats, and threat mitigation	
12.1.	Side-effects during study execution	Deviations from the plan, solutions for the deviations	
13.	Most important findings	Are all study questions answered [29]? Are negative findings presented [29]?	
14.	Industry impact, inference, generalisation	What implications does the report have for practice [29]? How and where the results can be used? Limitations under which findings are relevant [35]?	
15.	Future work
