
Abstract

Context. Prioritization is essential part of requirements engineering, software release planning and many other software engineering disciplines. Cumulative Voting (CV) is known as relatively simple method for prioritizing requirements on a ratio scale. Historically, CV has been applied in decision making in government elections, corporate governance, and forestry. CV prioritization results are special type of data – compositional data.

Objectives. The purpose of this study is to aid decision making by collecting knowledge on the empirical use of CV and developing a method for detecting prioritization items with equal priority.

Methods. We present a systematic literature review of CV and CV result analysis methods. The review is based on search in electronic databases and snowball sampling of the primary studies. Relevant studies are selected based on titles, abstracts, and full text inspection. Additionally, we propose Equality of Cumulative Votes (ECV) – a CV result analysis method that identifies prioritization items with equal priority.

Results. CV has been used in not only in requirements prioritization and release planning but also in software process improvement, change impact analysis, model driven software development, etc. The review has resulted in a collection of state of the practice studies and CV result analysis methods. ECV has been applied to 27 prioritization cases from 14 studies and has identified nine groups of equal items in three studies.

Conclusions. We believe that collected studies and CV result analysis methods can help the adoption of CV prioritization method. The evaluation of ECV indicates that it is able to detect prioritization items with equal priority.

Cumulative voting, Hundred-dollar test, \$100 test, requirements prioritization, Systematic review

1. Introduction

Software products are becoming larger and more complex. Each product is usually affected by a large number of factors such as product functional requirements, quality attributes, or software process improvement issues. Since time, funding, and resources are limited, it is seldom possible or efficient to fully address all the factors. Therefore, the level of attention to a particular factor should be decided according to its importance (i.e. business value), cost, risk, volatility, dependencies between the factors and other criteria. These type of decisions are made by product stakeholders: users, clients, managers, sponsors, developers, and other persons associated with the product. In order to make decisions regarding a large number of factors it is highly advisable to prioritize the factors in a systematic way [1].

One of the prioritization methods used in software engineering is Cumulative Voting (CV) [2]. The main advantage of CV is that it is relatively simple and fast, yet produces priorities in ratio scale [1, 3]. This allows us not only to determine what prioritization items are more important but also how much more important they are. (Ratio scale prioritization is particularly important in software release planning and cost-value analysis [4, 5].)

Prioritization is usually performed by multiple stakeholders where individual priorities are combined into a single priority list. Each stakeholder's preferences may have different weight in the final priority. Such prioritization provides more information than just the priorities of factors. It may be useful to analyze the results of the prioritization to assess disagreement between stakeholders, measure stakeholder satisfaction with the results or find distinct groups of stakeholders.

The purpose of this study is to help industry practitioners and academia researchers in adopting, using and developing CV, while the importance of prioritization in software engineering and the prospectiveness of CV constitutes a need to do further research in this area.

This study presents a systematic literature review of the empirical use of CV and CV result analysis methods. A new method for CV result analysis, called Equality of Cumulative Votes (ECV), is proposed. The method identifies prioritization items with *equal* priority. ECV is evaluated using a considerable amount of data, which was obtained from the primary studies identified by the systematic review (through the kindness of the authors of said studies).

The remainder of this paper is structured as follows. The background is presented in Section 2. Section 3 describes related studies. In Section 4 research questions and methods are presented. The design of the systematic

40 review is presented in Section 5 and ECV is presented in Section 6. Section 7
41 presents the results of the study and Section 8 is a discussion section.

42 **2. Background**

43 This section presents definitions and places this study in a context. In the
44 coming sections we will cover: a description of software requirements priori-
45 tization methods; examples of CV result analysis methods; and a description
46 of compositional data analysis and CV.

47 *2.1. Prioritization Methods*

48 Some of the most popular prioritization methods are the analytical hi-
49 erarchy process (AHP), cumulative voting (CV), ranking, numerical assign-
50 ment, top-ten, the planning game, minimal spanning tree, bubble sort and
51 binary search tree [1, 6]. Ranking and numerical assignment methods per-
52 form prioritization on an ordinal scale. AHP and CV are, on the one hand,
53 considered to be harder to use and also more time consuming compared to
54 other methods but, on the other hand, produce priorities in ratio scale.

55 Prioritization can be used not just to decide which factors to address, but
56 also to determine the order in which they need to be handled. In market-
57 driven software development a small part of a very large number of require-
58 ments need to be selected and divided into several releases to maximize return
59 on investment. While in bespoke requirements, focusing on early delivery of
60 value can help reduce the risk of project cancellation.

61 Ratio scale priorities have several advantages over ordinal scale priori-
62 ties. Ratio scale shows not just the order of items but also relative distance
63 between them. This enables the priority of a group of items to be calculated
64 by summing up the priorities of individual items [4]. It is possible to say
65 that one item or set of items has higher priority than another set of items.
66 Supposing stakeholders have to choose between several low priority items
67 and one item with higher priority; with ordinal scale, the item with high-
68 est priority will always be selected first. However, if priorities are given on
69 a ratio scale, it is possible that lower priority items will be selected if their
70 cumulative priority is higher. Knowing the relative importance of sets of pri-
71 oritization items helps in software release planning. Ratio scale allows the
72 combining of multiple priority factors by calculating ratios between them.
73 One example of this is the cost-value ratio that shows which requirements
74 give more value for less money [5].

75 2.2. Prioritization Result Analysis

76 Different studies use and analyze CV in different ways. Disagreement
77 between stakeholders happens when two or more stakeholders have assigned
78 a different priority to one prioritization item. If the level of disagreement is
79 high it may indicate potential conflicts between stakeholders. Such conflicts
80 may be of technical character, as well as social or cultural.

81 The satisfaction a stakeholder has with the final prioritization results is
82 determined by the difference between the results and the individual priorities
83 of the stakeholder. A smaller level of difference leads to higher satisfaction.
84 In the end, stakeholder satisfaction is important because it is necessary to
85 achieve stakeholder commitment.

86 In some cases a part of stakeholders may form a group of some kind and,
87 therefore, prioritize requirements similarly. It may be useful to detect whether
88 a group of stakeholders has different preferences than all other stakeholders.
89 As an example, in [7] domain experts, technical experts, managers, project
90 managers, testers, and developers use CV to prioritize software process im-
91 provement issues and the CV results are analysed using disagreement charts
92 and satisfaction charts. Finally, principal component analysis (PCA) is used
93 to identify distinct groups of stakeholders.

94 The same items can be prioritized by the same stakeholders multiple
95 times from different perspectives. In this case it is useful to determine corre-
96 lation between the priorities in different perspectives to assess the differences
97 between the perspectives. As an example, in [8] CV is used by developers,
98 testers, and managers to prioritize quality attributes. The same quality at-
99 tributes are prioritized from two perspectives: the perceived situation today
100 and the perceived ideal situation. Correlation between the two perspectives
101 is evaluated using the Spearman rank correlation matrix. This allows an
102 analysis of how well the company balances the priorities of software quality
103 attributes.

104 In [9] change impact issues are prioritized by developers, testers, man-
105 agers, and system architects. The prioritization is done with respect to three
106 perspectives: strategic, tactical, and operative. In order to determine corre-
107 lation between the perspectives, CV results are analysed using the Kruskal-
108 Wallis test. In [10] the results of [9] are further analysed using PCA, bi-plot,
109 and ternary plot. In this case, PCA is used to find correlated issues, bi-
110 plot shows variance, correlation, difference between the priorities of issues,
111 and the viewpoints of stakeholders, while ternary plots are used to show the
112 relative number of issues that received high, medium, and low priority.

113 As can be seen above, from the examples given, prioritization has been
114 performed with various stakeholders, using different perspectives and, in the

115 end, also analysed using various techniques. We will next describe in more
116 detail one of the more common methods to manage prioritization issues —
117 cumulative voting — which has been used in software engineering for some
118 time, but has its roots in corporate governance and biology.

119 *2.3. Cumulative Voting*

120 CV is a prioritization method for prioritizing a list of items [2]. CV has
121 many synonyms in literature: hundred dollar method, hundred dollar test,
122 hundred point method, 100\$ dollar method, 100\$ dollar test, 100\$ point
123 method. Before being applied in software engineering CV was used for polit-
124 ical elections [11] and corporate governance [12]. CV has also been applied
125 in e.g. decision making in forestry [13], voting in social networks [14] and in
126 computer algorithms for consensus clustering [15] (as a method for combining
127 the results of different clustering algorithms).

128 In CV a stakeholder is given 100 points, imaginary dollars or units of
129 percentages that can be spent on the prioritization items. In the simplest
130 case, the stakeholder can spend any amount of points on any number of items
131 as long as the total amount adds up to 100. The more points assigned to an
132 item, the higher the priority of the item (and implicitly, the lower priority
133 to the other items). The stakeholder may spend all the points on just one
134 item or distribute them among all or some of the items. Once again, this is
135 the simplest case; other variants exist, which we will see next.

136 Often prioritization is done by more than one stakeholder. The final
137 priority of an item can be calculated by adding up the points each stakeholder
138 has spent on it. Sometimes the vote of some stakeholders may be more
139 important than the votes of others. For example, a manager may be more
140 influential and shareholders may have different amount of shares. In such
141 a case the priorities of each stakeholder may be multiplied by an individual
142 coefficient or a different amount of points for prioritization.

143 Worth mentioning in this context is that it is advisable to randomize the
144 order of items in a prioritization list. This is necessary in order to minimize
145 the effect of order on the prioritization results, which has shown to have an
146 effect [16].

147 *2.3.1. Benefits and Drawbacks of Cumulative Voting*

148 Compared to analytical hierarchy process (AHP), CV is faster and easier
149 to learn and use [1, 3]. AHP benefits from consistency check, but CV does
150 not require this because all prioritization items are evaluated simultaneously
151 [3].

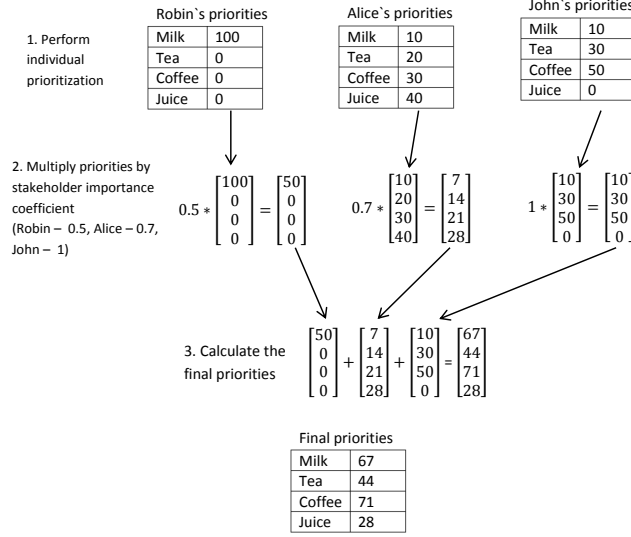

Figure 1: Example of CV with several stakeholders.

152 There are, however, a few problems with CV. First of all, it cannot be
 153 repeated for the same stakeholders and prioritization items due to stake-
 154 holder bias [2] (c.f. Section 2.3.4). Secondly, CV becomes more difficult if
 155 the number of prioritization items increases [17].

156 2.3.2. Example of Cumulative Voting with Several Stakeholders

157 Let us give an example of CV with several stakeholders. Suppose Robin,
 158 Alice, and John are three friends who want to buy some beverages in a store.
 159 They have different preferences but do not want to buy too many drinks.
 160 Therefore, they decide to use CV to decide what to buy. Each of the friends
 161 distributes 100 points between four items: milk, tea, coffee, and juice (Step
 162 1 in Figure 1). Each of them will spend a different amount of money on
 163 the purchase, hence, their priorities are multiplied by different coefficients
 164 (Step 2 and the stakeholder importance coefficient in Figure 1). The final
 165 beverage priorities are calculated by summing up the weighted priorities of
 166 stakeholders (Step 3 in Figure 1).

167 2.3.3. Stakeholder Bias

168 Prioritization using CV may be biased if a stakeholder knows the pref-
 169 erences of other stakeholders. She may manipulate the results by spending

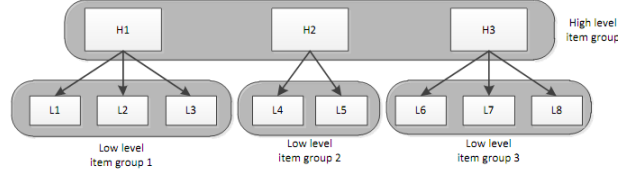

Figure 2: Example of prioritization item hierarchy.

more points on items that are important to her but not the other stakeholders. On the one hand, stakeholder bias makes it unreasonable to repeat CV with the same prioritization items and stakeholders. On the other hand, this property of CV may be useful in giving more power to important minority stakeholders, such as security experts or software testers. Suppose the same software requirements are prioritized for a second time using CV. A developer might know that all vital functionality is selected by other stakeholders, but his toy feature is left out. In effect, the developer could spend all his points on this feature to put it in the next release.

Stakeholder bias may be mitigated by setting a maximum priority that can be assigned to an item. This way each stakeholder is forced to distribute the money between several prioritization items [4].

Another bias is that people in general tend to assign round priority values. This is likely caused by lack of objective judgement criteria. Either way it seems to be a problem not acknowledged by many since all prioritization is largely based on expert opinion.

2.3.4. Scalability of Cumulative Voting, Hierarchical Cumulative Voting

The standard CV approach has a low scalability. If the number of prioritization items is high, stakeholders may lose sight of the bigger picture and assign priorities to a limited number of items. One, unsophisticated, solution to the problem is to provide more points for prioritization (1,000 or 10,000 instead of 100); however, one could take another approach.

When the number of prioritization items is high they can usually be grouped hierarchically by forming a tree structure (Figure 2) and, thus, parent-child dependencies will exist between many items.

In [4] the authors propose a method for prioritizing hierarchically structured items called Hierarchical Cumulative Voting (HCV). It may be seen as combination of the hierarchical part of the Analytical Hierarchy Process (AHP) [1, 18] and the CV prioritization method. Since items are prioritized in smaller sets, stakeholders do not lose sight of the bigger picture during

200 prioritization, and the prioritization of a large number of requirements is
201 considered easier.

202 2.3.5. *Compensation Factors*

203 HCV deals with the problem of prioritization scalability but it comes at
204 a cost. Low level item groups may consist of different numbers of items, but
205 the number of points spent on each group is the same, i.e. in a small-sized
206 group, the same amount of points is distributed among fewer items. Hence,
207 items in smaller groups are statistically more likely to have a higher priority,
208 on average, compared to items in larger groups. To balance this difference
209 each low level prioritization item can be multiplied by a compensation factor
210 [4].

211 As an example, suppose an item (A) in a group of 10 items is assigned
212 60 points. Hence, A will receive 600 compensated points. In this case it is
213 impossible for any item in a group smaller than 6 items to compete with A .
214 Even if item (B) in a group of 5 is assigned the maximum number of points
215 (100), the maximum compensated priority value B can receive is 500.

216 In [17] the authors suggest that compensated prioritization is more fa-
217 vorable compared to uncompensated. But neither compensated nor uncom-
218 pensated prioritization is perfect and, as a general rule, it is better to keep
219 the size of prioritization item groups similar.

220 2.3.6. *HCV Execution*

221 According to [4], HCV is conducted with the following steps (Steps 4–5
222 are optional):

- 223 1. Construct hierarchy. Prioritization items need to be divided into one
224 high and several low level item groups. Each low level item group is
225 child to exactly one high level item. And each high level item has
226 one low level item group. One low level item may belong to several
227 item groups. Even if part of the items are not logically connected they
228 can be grouped separately and assigned a fake parent item, e.g. ‘misc.
229 items’. HCV does not, as far as we know, provide any directions on
230 creating a requirements hierarchy.
- 231 2. Each high and low level item group is prioritized separately using CV.
232 The stakeholder may prioritize all item groups at once or one by one.
233 But it should be possible to prioritize groups in any order and repeat-
234 edly, because the stakeholder might learn more about the items while
235 performing the prioritization.
236 In particular the stakeholder is likely to learn more about a high level
237 item when prioritizing its low level item group [19]. Some stakeholders

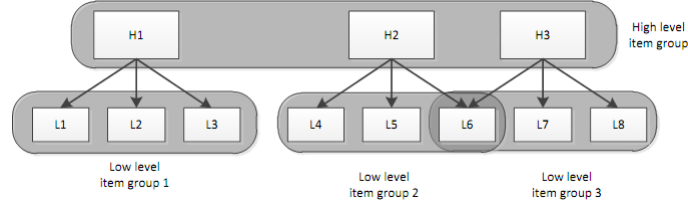

Figure 3: Overlapping prioritization item hierarchy example.

- may prioritize only part of the groups and each group may be prioritized by different stakeholders.
3. The priority of each low level item is normalized by dividing it with the sum of all low level priorities of each item in all groups.
 4. The final priority of each low level item is calculated by multiplying it with the priority of its parent high level item.
 5. Then apply the compensation factor to all low level requirements as described in Section 2.3.5.
 6. Finally, when multiple stakeholders have performed the prioritization, priorities of low level items are combined as in standard CV.

It is possible that one low level item is child of more than one high level requirement and, thus, belongs to two or more low level requirement groups (see Figure 3). Such requirements participate in the standard HCV prioritization process and are prioritized two or more times with each group they belong to. At the end of the prioritization they receive several priority values. These values can be summed together to form the final priority of the item. (This is done because the item adds value to both parts of hierarchy.)

2.3.7. Example of Hierarchical Cumulative Voting

In this section we will give a short example of HCV. Suppose six requirements for a mobile phone operating system need to be prioritized: ‘reminder alarm’, ‘specify repeated event’, ‘hide contact’, ‘add picture to phonebook’, ‘search contact’, ‘make video call’. Three high level requirements can be identified: ‘Calendar’, ‘Phonebook’, ‘Call’. The low level requirements are then grouped as sub-requirements of high level requirements as shown in Figure 4. The ‘Search contact’ requirement is a sub-requirement and has two parent requirements: ‘Phonebook’ and ‘Call’. The computation of the final priorities of requirements is shown in Table 1.

After requirements are grouped, and a hierarchy is defined, each group of requirements are then prioritized using CV. The final priority of a low level

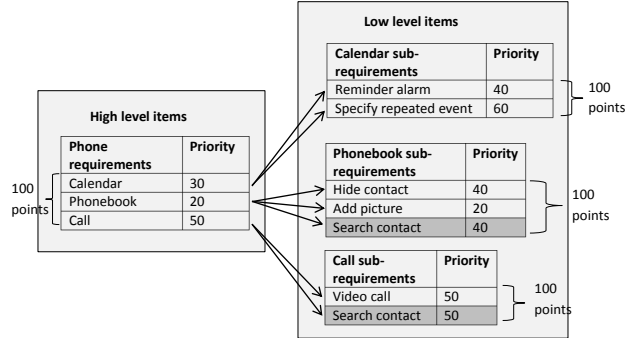

Figure 4: Example of hierarchical cumulative voting, requirement hierarchy

Table 1: Example of hierarchical cumulative voting.

Phone requirements	Compensation factor	Sub-requirements	Priority calculation	Final priority
Calendar	2	Reminder alarm	$40 \times 30 \times 2$	2400
Calendar	2	Specify repeated event	$60 \times 30 \times 2$	3600
Phonebook	3	Hide contact	$40 \times 20 \times 3$	1600
Phonebook	3	Add picture	$20 \times 20 \times 3$	800
Phonebook & Call	3 & 2	Search contact	$40 \times 20 \times 3 + 50 \times 50 \times 2$	7400
Call	2	Video call	$50 \times 50 \times 2$	2500

requirement is computed by multiplying the priority of the requirement with the priority of its parent high level requirement and the compensation factor. The compensation factor in this particular case is the number of elements in a group, two for the ‘calendar’ and ‘call’ sub-requirements and three for the ‘phonebook’ sub-requirement.

2.4. Compositional Data Analysis

CV results can be seen as a special type of data, i.e. compositional data. Compositional data does not contain absolute values. It shows only the relative weight of a component in a whole. In [10] the authors propose the use of compositional data analysis for the statistical analysis of CV.

A compositional data item is a vector (x) of positive components with a constant sum k :

$$x = (X_1; X_2; \dots; X_n) \text{ where } x_i \geq 0 \text{ and } \sum_{j=1}^n x_j = k. \quad (1)$$

279 The property of the sum of the items being restricted is called the con-
280 stant sum constraint. In CV, priorities assigned by a stakeholder to the
281 items of a prioritization set is a compositional data vector with a constant
282 sum of 100. The value of k (i.e. 100 in this case) is arbitrary and does not
283 affect the analysis of the data because the information is contained in the
284 ratios between the components of the vector. The vector can sum up to any
285 number but still hold the same data, i.e. vectors (1, 2, 7) and (10, 20, 70)
286 are in this case considered equivalent.

287 The priority of an item is relative to the priority of the other items in
288 the set. Hence, the priority of an individual item is meaningless without
289 context, i.e. the complete set of items. The same item may receive different
290 priority when put in two different prioritization sets. If the item is put in a
291 set of items with high priority it will receive a lower relative priority. This
292 also holds true the other way around i.e. if the item is put in a set with low
293 priority items its priority will be higher.

294 When doing analysis of compositional data one must take into account
295 that compositional data is special and should be analysed differently than
296 ordinary data. Ordinary unconstrained variables are free to take any positive
297 or negative values, whereas, compositional data values can only be positive
298 and have a constrained maximum value. Moreover, components of compo-
299 sitional data vectors are not independent from each other. The fact that an
300 item is assigned 70 priority points means that the next item can take only
301 values between 0 and 30. Hence, there is a negative correlation between the
302 items.

303 Standard parametric statistical tests require that data vectors have mul-
304 tivariate normal distribution. Vector $X = (X_1, X_2, \dots, X_n)$ is considered to
305 have multivariate normal distribution if any linear combination of its parts
306 is normally distributed, and linear combination is defined by:

$$Y = a_1X_1 + a_2X_2 + \dots + a_nX_n, \quad (2)$$

307 where Y is the product of lineal combination and a_i is any real number.
308 Now, since the sum of priorities assigned in CV must add up to 100 (or any
309 other constant number) at least one linear combination of X is not normally
310 distributed because it always adds up to 100:

$$Y = 1 \cdot X_1 + 1 \cdot X_2 + \dots + 1 \cdot X_n = 100. \quad (3)$$

311 In our opinion, the above indicates, quite strongly, that CV results do
312 not follow a multivariate normal distribution and, hence, it follows that they
313 should be analysed using non-parametric statistical tests [20].

314 2.4.1. Problem of Zeroes

315 Compositional data analysis requires that log-ratios between any com-
 316 ponents in a vector can be computed. But computing a log-ratio with a
 317 zero value is, in this case, meaningless. This is a problem since CV allows
 318 stakeholders to assign zero priorities to some prioritization items (we would
 319 even strongly argue that this is very common).

320 In compositional data there are two types of zeroes: essential and rounded.
 321 Essential zeroes mean that a data component is not present. Rounded zeroes
 322 mean that the component is present but its value is very low. We, as others
 323 have before us, conjecture that zeroes in CV results are rounded because the
 324 priority of an item is a completely abstract notion and the instrument for
 325 measuring priority is human judgement [10].

326 Before compositional data analysis can be applied to CV results, we
 327 should first remove zeroes in the data. One approach can be to forbid stake-
 328 holders to assign zero priorities. This approach is used in e.g. [7]. But this
 329 can add some unnecessary complexity to the prioritization process and, ex-
 330 plicitly, delimits an expert's freedom. In [10] the authors propose the use
 331 of a multiplicative replacement strategy (as defined in [21]) for CV result
 332 analysis.

This method replaces rounded zeroes with small values using the expres-
 sion

$$r_j = \begin{cases} \delta_j, & \text{if } x_j = 0, \\ (1 - \frac{\sum_{k|x_k=0} \delta_k}{c})x_j, & \text{if } x_j > 0, \end{cases} \quad (4)$$

333 where δ_j is the imputed value and c is the constant sum constraint.
 334 In order for the total sum of components to stay constant, the equation
 335 subtracts some value from the items with a priority higher than zero. More
 336 is subtracted from components with higher values than from components
 337 with lower values (and the value of the imputed δ_j is arbitrary).

338 2.4.2. Isometric log-ratio transformation

339 In order to apply standard statistical methods to compositional data
 340 it should be transformed to remove the inherent correlation of the values.
 341 Compositional data analysis proposes special transformations that change
 342 the compositional data values to unconstrained real values. One such trans-
 343 formation is isometric log-ratio (*ilr*) transformation (as proposed by [20, 22]):

$$\begin{aligned}
z &= (z_1, \dots, z_{D-1}), \\
z_i &= \sqrt{\frac{i}{i+1}} \log \frac{\sqrt[i]{\prod_{j=1}^i x_j}}{x_{i+1}} \text{ for } i = 1, \dots, D-1,
\end{aligned} \tag{5}$$

where x is the vector that is being transformed and z is the vector that is created. It should be noted that z is shorter than x by one element.

After compositional data vectors are transformed using zero replacement and *ilr*, any standard statistical tests can be applied.

3. Related Work

A systematic review of requirements prioritization methods is presented in [23]. The study focuses on prioritization method comparison and selects eight relevant studies. Two of the studies use CV. These studies are also revealed by the systematic literature review conducted as part of this study. Khan [23] concludes that there is little research on requirements prioritization and studies usually deal with a small number of requirements.

The systematic literature review presented in this paper does not reveal any CV result analysis methods that allows to identify prioritization items with equal priority. Thus, this problem is not addressed in any way.

4. Methodology

This section covers the research questions of this study and the methods used to answer them.

4.1. Selection of Research Methods

The main purpose of this study is to collect knowledge on the use of CV in order to help software engineers and researchers in adopting it.

One way of collecting this knowledge is to conduct an empirical study. A survey in a large number of software companies can be used to quantify the level of adoption of CV in industry (similarly to the study by [24]), while a case study can be used to receive qualitative feedback on the use of CV [25].

Knowledge on the empirical use of CV can also be obtained from existing studies. This may be done by means of a systematic literature review. Several studies have used CV in industry as well as in academic settings. Nevertheless, there are no studies that provide an overview of the current state of the practice in this field (as reported by research studies). Therefore,

373 before continuing with the refinement of CV and conducting new empirical
374 studies (i.e. case study or experiment), a systematic literature review would
375 be required.

376 This paper proposes a new method for CV result analysis, called Equality
377 of Cumulative Votes (ECV). (ECV groups prioritization items into groups
378 of items with similar priority.) As will be presented later, the systematic
379 review did not reveal any methods that solve this problem; however, ECV
380 needs to be evaluated and, hence, applied to CV results.

381 There are two options to obtain CV results in order to test ECV. One
382 is to conduct a new empirical study. The second option is to collect CV
383 results from existing studies. The latter approach also has the added ben-
384 efit of trying to replicate the results from previous studies and, if the CV
385 results from other studies are used, a larger amount of data can be obtained.
386 Moreover, the generalizability of the evaluation increases when prioritization
387 results from different sources and domains are used. On the other hand, the
388 main benefit of conducting a separate empirical study is the possibility to
389 control the conditions of CV.

390 In our study we evaluated ECV by obtaining data from previously con-
391 ducted studies as found by the systematic literature review. In order to
392 obtain the data, authors of relevant primary studies were contacted.

393 In short, this study consists of two parts: a systematic literature review
394 (SLR) of CV and an evaluation of ECV based on the data from the primary
395 studies found in the SLR.

396 *4.2. Research Questions*

397 The systematic review should focus on catching studies that empirically
398 use CV. Information about place, time, scale, and domain of the studies
399 should be collected and the results of the review will hopefully aid academic
400 researchers by identifying paths for further investigation of CV. Hence, the
401 first research question is:

402 **RQ 1.** What is the state of practice in empirical studies that use CV?

403 The level of trust in research results considering CV is determined by the
404 quality of the studies that use CV, hence this study includes an evaluation
405 of the quality of primary studies identified by the systematic review.

406 Next, a valuable aspect of decision making is the analysis of prioritization
407 results. Thus, the second research question is:

408 **RQ 2.** What CV result analysis methods have been presented in papers as
409 identified by RQ 1?

410 Finally, the evaluation of ECV answers the third research question:

411 **RQ 3.** Is ECV capable of identifying prioritization items with equal prior-
412 ity?

413 5. Systematic Literature Review

414 This section presents the design of the systematic literature review. For
415 the results of the execution please see Section 7.1 and 7.2.

416 Table 2 presents an overview of activities performed during the system-
417 atic literature review. The review protocol was developed by one researcher
418 and evaluated by another researcher. Studies were searched for in two itera-
419 tions. The first search was performed by using databases. The second search
420 was performed using snowball sampling [26] (snowball sampling examines the
421 references of primary studies revealed by the first search). References that
422 are relevant to the review, i.e. they pass the selection criteria, are then added
423 to the set of primary studies.

424 The search for papers was performed by a single researcher. Study se-
425 lection, on the other hand, was performed by two researchers. First, one
426 researcher examined all found studies. Next, another researcher re-examined
427 all studies classified as primary studies in addition to 20 randomly selected
428 excluded studies to ensure the quality of the selection.

429 To ensure the quality of the review, the quality evaluation and data ex-
430 traction was performed independently by two researchers. Inter-rater anal-
431 ysis was performed using Krippendorff’s Alpha statistics [27, 28].

432 5.1. Data Sources and Search Strategy

433 This SLR was designed based on the guidelines by Kitchenham [29]. First
434 a trial search in electronic databases was conducted. In order to scale the
435 review to a manageable, yet sufficient size, databases were searched with
436 different search strings. Relevant papers that were found during the trial
437 search were used to extract additional search strings. The trial search re-
438 vealed that the number of studies that use CV is not very large. Therefore,
439 we decided to include not only software engineering studies but also studies
440 in other research areas, such as forestry or corporate governance, since one
441 key aspect we intended to investigate was analysis methods for CV.

442 Since CV is frequently used in studies without mentioning this in the
443 abstract, full text search in databases is preferable. Unfortunately not all
444 databases support full text search. Full text search was performed in the

Table 2: Review activities.

Review phase		Researchers involved
Trial search in databases		A
Develop review protocol		A
Evaluate review protocol		B
Paper search and selection from databases	Search in databases	A
	Search string validation	A
	Selection based on metadata	A and B
	Selection based on full text	A and B
Pilot data extraction (3 papers)		A
Paper selection from the reference lists	Selection based on metadata	A and B
	Selection based on full text	A and B
Data extraction		A and B
Data synthesis		A

A – Cumulative voting	E – hundred dollar method
B – 100 dollar method	F – hundred dollar test
C – 100 dollar test	G – hundred point method
D – 100 point method	

445 IEEE Xplore and Springer Link databases. In ACM Digital Library, In-
 446 spec/Compendex, ISI Web of Knowledge, and SCOPUS only metadata was
 447 searched. Search strings consisting of a Boolean expression (A or B or C or
 448 D or E or F or G), where:

449 Search strings contained only synonyms of CV and they did not limit the
 450 research area to software engineering. The search was performed indepen-
 451 dently using each of the search strings in each database. All search results
 452 were combined and documented using reference management software. The
 453 quality of the search strings and the selection of electronic databases were
 454 validated against a previously known core set of papers—[3, 30, 10, 31]—
 455 checking that all papers from the core set were found by the search.

456 5.2. Study Selection

457 To select relevant papers a set of criteria were designed. The criteria for
 458 paper selection are presented in Tables 3 and 4.

459 Papers were selected in two phases: based on metadata and based on full
 460 text.

461 Obviously, the main criterion for inclusion of a paper is that it must
 462 present empirical use of CV or present an analysis of the results of using
 463 CV. However, there are papers that pass this criterion but are not relevant
 464 for this review. CV is frequently used in computer algorithms. There is
 465 a significant difference between the way that humans and computers make
 466 decisions. Since this review is concerned with human decisions we excluded
 467 papers that present CV that is not performed by humans. In addition, only
 468 papers that were written in English were selected and duplicate studies were
 469 automatically excluded by the citation management software used in this
 470 review.

471 5.3. Quality Evaluation

472 The goal of quality evaluation is to determine the best primary studies
 473 according to some measure of quality. Since the number of studies that use
 474 CV is not large, quality evaluation was not used as an exclusion criterion.

475 Study quality obviously depends on the correctness of the study process
 476 including planning, operation, analysis and interpretation of the results (is
 477 the study right?) The correctness of the process can be measured by evalu-
 478 ating the description of the study or replicating the study. Thus, to gain the

Table 3: Paper search and selection in the databases.

Selection phase	Inclusion criteria	Number of papers selected
Search in databases	published from 2001 until 2011 (databases last accessed Feb. 20, 2011)	256
	contains search strings	
Selection based on metadata	exclude duplicates and tables of contents	177
	written in English	
Selection based on full text	full text is available	127
	study involves empirical use of CV or presents analysis of empirical use of CV	58
	CV is done by humans and not software	25

Table 4: Paper selection from the reference lists of the selected papers.

	study involves empirical use of CV or presents analysis of empirical use of CV	15
	CV is done by humans and not software	

479 trust of industry practitioners and other researchers, the process of the study
480 should be rigorously described. In short, the description has to facilitate the
481 replication of the study as well as the presentation of limitations and validity
482 threats.

483 Even the most correct and rigorously described study is useless if it does
484 not contribute to the industry or research community (is it the right study?)
485 The topic of the research ought to address important goals and issues. The
486 findings of the study should also be significant, i.e. there is a high probability
487 of the results of the study are true. The significance of the findings depends
488 on how realistic the study is, the correctness of the process and the results
489 of the study, as well as the statistical significance of the findings.

490 **Realism** of a study depends on the context, scale, and subjects of the
491 study. The study should be conducted in a **setting** that is similar or equal
492 to the setting in which the findings of the study are intended to be used.
493 Hence, studies that are conducted in an industrial setting are in many cases
494 valuable. The **subjects** of a study should be similar to the people who are
495 supposed to use the findings of the study. The subjects ought to have appro-
496 priate work experience, role in the organization, skills, cultural background,
497 motivation, and so forth. The **scale** of a study refers to the size of the study
498 objects. In the case of this systematic review the scale of a study is mea-
499 sured as the number of prioritization items. Study in academia may have a
500 large number of prioritization items. At the same time, an industrial study,
501 with professionals as subjects, may involve a smaller number of prioritization
502 items.

503 Each study may have a different level of realism. Some studies involve
504 industry practitioners in an academic setting to simulate real word practice in
505 a laboratory environment. Other studies may involve academic researchers
506 that execute a project. For example, researchers may be developing open
507 source software. On the reality scale these studies are somewhere in between
508 the purely academic and industrial studies.

509 The **type** of the research study can be considered as a criterion for the
510 evaluation of study realism. Reference [32] suggest that study designs that
511 are more rigorous (e.g. experiments) are more realistic than observational
512 studies (e.g. case study) due to a higher level of control. On the other hand
513 [33] rate study designs based on other criteria, i.e. how frequently each type of
514 study design is used in an industrial or academic setting. If a study design
515 is used more in an industrial setting, then it is considered more realistic.
516 For instance, in software engineering, case studies are frequently used in
517 industrial settings, whereas, experiments are usually performed in academia
518 using students as subjects. Therefore, [33] argue that case studies are more

519 realistic than formal experiments. Obviously the effect of study design on
520 the study realism may be interpreted in different ways. Therefore, we will
521 not use this parameter in our quality evaluation.

522 The statistical significance of the results of a study can be used to eval-
523 uate the significance of the study findings. This measure will not be used,
524 because the studies that are evaluated belong to very different research areas,
525 i.e. the significance levels of the findings of the studies are not directly compa-
526 rable for meta-analysis. Additionally, sometimes no result is more interesting
527 than a significant result. If study results do not conform to the expectations
528 of researchers, this may reveal important gaps in existing knowledge.

529 The ultimate goal of research, at least in software engineering, is in many
530 cases industry impact. However, most of the time ideas need to be developed
531 and validated in academia before industry professionals will risk to adopt
532 them. Therefore, academic impact is important as well. Academic impact
533 is usually measured by the number of citations. Academic impact is also
534 measured for particular researchers, using the number of papers she has
535 published and the number of citations of her papers. This measure will
536 not be used in our quality evaluation because it is somewhat biased. The
537 number of citations is likely to be lower for newer papers and the number
538 of papers that a researcher has published gives little information about the
539 actual quality or impact of her research.

540 5.3.1. *Rating of the Studies*

541 The quality evaluation in our review is based on the evaluation of: (i)
542 Study realism. (ii) Study scale. (iii) Availability of raw results of CV. (iv)
543 Quality of the research methodology.

544 Realism of the studies is rated in three aspects: subjects, setting, and
545 scale. The subjects and setting is rated according to Table 5. The total
546 rating of study realism is determined by summing up the ratings of the two
547 aspects. For instance, if a study is conducted with industry professionals
548 as subjects in an academic context the study will receive rating 1 (out of 2
549 maximal points).

550 In order to rate the scale of a study the number of prioritization items
551 was counted. If a paper presents several prioritization cases only the prior-
552 itization with the largest number of the prioritization items is considered.
553 If HCV is used all of the prioritization items on different levels are counted
554 together. However, if an item is present in several groups in the hierarchy it
555 is counted only once.

556 The availability of raw results of CV is rated separately because it is
557 especially important for our purposes (and for most other researchers in

Table 5: Rating of study reality level

Aspect	Contribute to relevance (rating 1)	Do not contribute to relevance (rating 0)
Subjects	Industry professionals	Academia students or teachers, or other
Context	Industrial	Academia

Table 6: Research data availability rating

Rating	Study rating criteria
0	CV results was not provided in the paper and we was unable to obtain the results from the authors.
1	CV results are not provided in the paper but the data was obtained from the authors. Part of the data is lost or corrupted.
2	CV results are not provided in the paper but all the data was obtained from the authors.
3	All CV results are included in the paper or reference is given to online source where all the data can be accessed.

order to replicate a study). The data availability rating criteria is given in Table 6. If the data of a study are not available it is not possible to validate the results of the study and, hence, the credibility of the findings is lower. Ideally the data collected in the study should be presented directly in the paper. An alternative may be to make the data freely available online and reference the online source.

The quality of the research methodology of a paper is rated according to a checklist presented in Appendix C. The checklist is based on guidelines for presenting research studies as presented in [34, 35] and the guidelines for quality evaluation of research studies presented in [33, 29]. Evaluation is done with regard to the rigor of the description and correctness of the research process and reasoning. Checklist items represent issues that research studies should implement and present in research paper. The checklist also contains item descriptions or questions that are used to evaluate the quality. Each item in the checklist is rated according to criteria presented in Table 7. The final rating of correctness of the research process of a study is computed by summing up the ratings assigned to all items in the checklist.

Study rating criteria was validated during a trial data extraction. Two researchers each rated three randomly selected papers. Afterwards, differences in ratings were discussed and study rating criteria were updated to avoid differences in interpretation.

As a result of the rating each study was assigned four rating values on an ordinal scale. In order to perform a more advanced analysis of the quality evaluation results these ratings were then converted into ratio scale ranks.

Table 7: Rating of correctness of research process

Rating	Study rating criteria
0	No description provided.
1	Only basic information is provided about the checklist item. Or significant validity threats exist with regard to this item.
2	Description is sufficient. Some minor questions are left unanswered. Validity threats may exist but they are not likely to affect the results of the study.
3	Description is rigorous and clear. Questions presented in quality evaluation checklist in Appendix C are answered. Decisions of the study are well justified, alternatives are discussed. No unhandled validity threats can be identified.

Table 8: Example of rating values

Study	Realism	Research data availability	Correctness of research process	Number of prioritization items
ST1	2	0	15	6
ST2	1	3	20	69
ST3	0	3	10	6

For each study, the number of studies that have received lower ratings is counted. The resulting number is the rank of the study; thereby, the quality of a study is expressed as four rank values.

An example of rating values is shown in Table 8. Table 9 shows ranking values computed for the studies in Table 8. We can observe that study realism level rating for ST3 is 0. There are no studies that have a lower study realism. Therefore, realism ranking for ST3 is 0. ST1 on the other hand has the highest realism rating. Since ST1 has higher reality level than both ST2 and ST3 it is assigned reality level rank 2.

5.4. Data Extraction

The goal of data extraction is to understand how and why CV is used and how CV results are analysed in research studies. Ultimately, this will allow us to answer the first and second research questions in our study.

Data extraction was documented with the help of spreadsheet software. Extracted data items are available from [36].

Table 9: Example of ranking values

Study	Reality level	Research data availability	Correctness of research process	Number of prioritization items
ST1	2	0	1	0
ST2	1	1	2	2
ST3	0	1	0	0

597 6. Equality of Cumulative Votes

598 In the previous section we described the execution of the systematic lit-
599 erature review. In order to perform a more thorough analysis later we here
600 present the design of ECV before presenting the results of the systematic
601 literature review. For the results of the evaluation of ECV please see Sec-
602 tion 7.3 (ECV is implemented in the *R* programming language [37] and the
603 code can be found at [38].)

604 In CV stakeholders may assign similar or equal values to several prior-
605 itization items. As a result the difference between the items is small. The
606 variation in priorities is caused not only by the difference between priorit-
607 ization items but also by human error and lack of information for decision
608 making. For instance, people tend to simplify the task of prioritization by
609 assigning rounded values to items or giving equal values to several items [39].

610 During prioritization it may be beneficial to know which items are equal.
611 A common example is software release planning where requirements are dis-
612 tributed among several product releases. If two or more requirements are
613 considered equal they can be freely interchanged between the releases, and
614 other criteria, such as cost or effort, may be used as sole indicators for plan-
615 ning that particular release.

616 6.1. Testing Equality of Two Items

617 There are two ways to determine which prioritization items have similar
618 priority. One approach is to find items that are different and consider other
619 items as equal. Another approach is to find items that are equal.

620 The first approach uses statistical tests to evaluate differences between
621 e.g. two population means, in order to determine that two items are different.
622 Populations in this case consist of priorities assigned by all stakeholders to a
623 particular prioritization item. The number of stakeholders that perform the
624 prioritization is frequently small. Hence, the size of the sample is very often
625 too small for statistical tests to detect a significant difference in the tests,
626 thus, identify too many equal items to make any useful conclusions.

627 ECV, in contrast, uses the second approach. It finds items that are
628 similar and the rest of the items are considered different. This method tests
629 the probability of the difference between the means of two items being smaller
630 than the given value. In short, ECV tests the probability of the means of two
631 prioritization items differing by less than 25%. If the probability is higher
632 than 70% the items are considered equal.

633 The input to ECV is an $n \times p$ matrix A that contains the raw results of
634 the prioritization. The columns of the matrix represent prioritization items

while rows represent stakeholders. ECV performs the following operations for the priorities of each of the two prioritization items:

1. Replace zeroes in CV results.
2. Transform the data using *ilr* transformation.
3. Determine distribution function using kernel density estimation.
4. Use the distribution function to find the probability that the difference between two prioritization items is smaller than 25%.
5. Form groups of equal prioritization items.

Since CV results are compositional data, zeroes in A are replaced with other values. This is done using the multiplicative replacement strategy which is described in Section 2.4.1. Next, two columns are extracted from matrix A to create the new matrix B :

$$B = [a_{*,k}a_{*,l}], \quad (6)$$

where a is an element of matrix A , and k and l are the columns that represent items that are tested for equality, "*" denotes all rows of corresponding column.

The *ilr* transformation is then applied to each row of the matrix B and the new vector C is obtained. The equation for calculating elements of C using *ilr* transformation is:

$$c_i = ilr(b_{i1}, b_{i2}) = \sqrt{0.5} \log(b_{i1}/b_{i2}), \quad (7)$$

where c_i is the i^{th} element of C and b_{i1} and b_{i2} are the first and second elements in the i^{th} row of B . Each value c_i represents a log-ratio between k and l . The mean of the values of C can be interpreted as an average log-ratio between the items that expresses the difference between the items.

After the data is transformed into log-ratios statistical test can be applied. The purpose of the test is to determine what the probability is of the relative difference between two prioritization items k and l being less than 25%. This means determining the probability of the log-ratio k/l between the items k and l as being in the range of $\frac{3}{4}$ to $\frac{4}{3}$. Or in terms of log-ratios it means determining the probability of $ilr(l, m)$ being between $ilr(3, 4)$ and $ilr(4, 3)$, where l is value from column k and m is value from column l . Hence, the objective of the test is to determine the probability of the sample mean (i.e. mean value of C) laying between the two values.

The probability that the mean takes a particular value can be expressed in the form of a cumulative distribution function. The probability of the

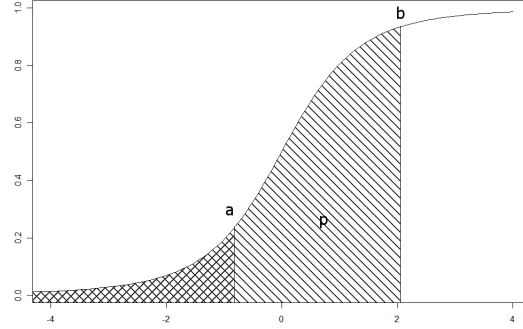

Figure 5: Cumulative distribution function of the log-ratio l/m between the items l and m (area p denotes probability that l/m is between $\frac{3}{4}$ and $\frac{4}{3}$.)

mean being between two values a and b (where a is smaller than b) can be determined by subtracting the probability of the mean being smaller than a from probability of the mean being smaller than b .

However, CV result data may or may not have multivariate normal distribution. If the data is normally distributed a Student's t distribution function can be used.

Otherwise a non-parametric estimation of the distribution function could be performed. In our case, the CV result data obtained from the primary studies identified by the systematic review, were tested for normality using the Anderson-Darling test. The tests we performed indicated, quite strongly, that in most of the prioritization cases the data is not normally distributed. Hence, our recommendation is that, in general, a non-parametric approach should be used to determine the probability density function, and one such, common, approach would be to use the kernel density estimation. (In our implementation of ECV in the R programming language, kernel density estimation is performed using the package *ks*.)

To determine the probability of \bar{x} being between a and b the following equation is used:

$$p = P(b) - P(a), \quad (8)$$

where P is the cumulative distribution function obtained by applying kernel density estimation on ilr -transformed priority values denoted by vector C . Variable a is equal to $ilr(3, 4)$ and b is equal to $ilr(4, 3)$. (A graphical interpretation of Equation (8) is presented in Figure 5.) The area that is denoted by letter p represents the probability computed by the equation.

After both prioritization items are tested for equality it may be conve-

Table 10: Example of equality table

prioritization items	i1	i2	i3	i4
i1	equal	equal	-	equal
i2	equal	equal	-	-
i3	-	-	equal	-
i4	equal	-	-	equal

nient to display the equality of different items in the form of a table. Please see Table 10 for an example.

6.2. Grouping Prioritization Items

When equal items are determined they can be divided into groups of equal items. Division is performed in such a way that each two items in a group are equal. The test for equality of the items described in Section 6.1 is not transitive. Hence, if prioritization item A is equal to B and B is equal to C then it does not automatically imply that A is equal to C . Therefore, there may be several ways to group the equal items. The two possible division criteria that we have considered in this study are:

1. Maximize the number of items that have a group.
2. Maximize the number of items in each group.

7. Results

This section presents the results of this study including the systematic literature review and the application of ECV on industry and academic data collected from the primary studies. Data extracted from primary studies and the results of the quality evaluation are available in [36].

7.1. State of Practice in Empirical Studies that use CV or Analyze the Results of CV (RQ 1)

The study search resulted in 634 unique studies. The search in databases revealed 180 papers, while an additional 454 papers were discovered using snowball sampling. The study selection resulted in 40 primary studies. Hence, 94% of the studies were excluded by the selection criteria. Snowball sampling revealed 15 or 36% out of all primary studies. The study selection criteria and the number of papers excluded by each criterion are shown in Tables 3 and 4. In total 163 of 634 studies were excluded because full text was not available.

719 All results of the study selection are available online and can be obtained
720 by contacting the authors of this paper. For each study we specify keywords
721 and databases that were used to find the study. If a study has been excluded,
722 the exclusion criteria are provided.

723 The number of papers revealed by each search string and database is
724 presented in Table 11. It should be noted that several papers were found
725 by more than one search string or in more than one database. Table 11
726 shows that the search string ‘cumulative voting’ was the most frequently
727 used in research community to denote CV. Therefore, researchers should use
728 or reference this term when discussing CV.

729 To perform snowball sampling we examined the references of primary
730 studies that were found during the database search. References were used
731 to search for the papers in the Google and Google Scholar search engines.
732 Studies that were found in the search and passed the study selection criteria
733 were added to the set of primary studies.

734 After the primary studies were selected, data extraction and quality eval-
735 uation was performed by two researchers. One researcher examined all stud-
736 ies while the second researcher did quality evaluation and data extraction for
737 10% of the studies. The studies were randomly selected. Inter-rater agree-
738 ment were calculated by means of Krippendorff’s alpha coefficient. Agree-
739 ment for data extraction results was 0.86 and agreement for the quality
740 evaluation was 0.73. According to [28] it is common to require agreement
741 above 0.8 and the lowest acceptable agreement is 0.667. Therefore, we con-
742 clude that the agreement calculated for this study is sufficient. Ratings of
743 the study setting, correctness, research data availability, and number of pri-
744 oritization items are presented in Figure 6.

745 Table 12 shows the studies with the highest quality according to our cri-
746 teria. These studies show a high level of rigor in a realistic setting. Moreover,
747 authors of the studies manifest confidence by providing raw data for further
748 use and evaluation.

749 Figure 7 shows a bubble chart of the distribution of studies over research
750 areas and time. The figure shows that CV was first applied some time
751 ago in research of government elections. Nowadays, though, CV has been
752 adopted in a wide range of software engineering areas. Most frequently in
753 requirements engineering and software release planning. Eight studies use
754 CV as a research method while the remaining 32 studies report on using CV
755 in industry.

7.2. CV Result Analysis Methods Identified by RQ 1 (RQ 2)

The papers identified in the review use various CV result analysis methods. The main goals for CV result analysis are presented in Table 13 and a summary of methods used in the primary studies can be found in Section Appendix B.

In order to present prioritization results many studies use charts or tables. These charts and tables show the average priority of each prioritization item that is computed from priorities assigned by all stakeholders. In [47] a table of five items with highest total priority is presented. [48] shows tables with min , max , \tilde{x} , \bar{x} and σ of priorities assigned by different stakeholders to a particular prioritization item. Finally, in [49, 48] error bars are added to the chart of final priorities (denoting σ of priorities).

In a few cases final priorities are presented in the form of ranks and CV results are degraded from ratio to ordinal scale. This is done when the interest lies only in the order of final priorities.

Several papers are interested in the difference between priorities from different prioritization perspectives (e.g. current and ideal situation) or stakeholder groups (e.g. software developers and management). Pearson or Spearman correlation coefficients are commonly used to determine what the level of similarity is between all priorities from two perspectives. Whereas, Wilcoxon, Kruskal-Wallis, Nemenyi-Damico-Wolfe-Dunn tests and the χ^2 statistic are used to detect if there is a significant difference in the value of one prioritization item from two or more perspectives. In addition, PCA is used to detect if there are distinct groups of stakeholders with common priorities [7, 10, 50].

In some cases, a stakeholder may assign equal priority to several prioritization items or leave several items unrated, e.g. the stakeholder may not have carefully considered all prioritization items. Hence, the difference between

784 the items may have been unnoticed.

785 In [4] the scalability of prioritization is measured using two charts. The
786 first chart shows the average percentages of items given a non-zero value.
787 The second chart shows average percentages of divergence of values. If a
788 stakeholder assigns equal priorities to many prioritization items the diver-
789 gence of values is low. Unfortunately it is unclear from [4] how the average
790 percentage of divergence is calculated.

791 In [51] distribution, disagreement, and satisfaction charts are presented.
792 The distribution chart shows how the final value of a prioritization item is
793 constructed from priorities assigned by different stakeholders. This chart
794 shows how much each stakeholder has contributed to the final value of a
795 prioritization item. The disagreement chart shows the level of agreement be-
796 tween different stakeholders on the value of a particular prioritization item.
797 The satisfaction chart shows stakeholder satisfaction with prioritization re-
798 sults by calculating the correlation between final priorities and priorities
799 assigned by a stakeholder.

800 The use of bi-plots and ternary plots are proposed in [10]. A bi-plot shows
801 final priorities and stakeholder viewpoints in a two dimensional plane while a
802 ternary plot shows prioritization items inside a triangle. Ternary plots show
803 how many low, medium or high priorities are assigned to a prioritization
804 item. The corners of the triangle represent high, medium, and low priority,
805 e.g. if a prioritization item has received mostly high priority values then it
806 is shown closer to the high priority corner.

807 7.2.1. *Problems with Compositional Data Analysis in Primary Studies*

808 A few primary studies, as revealed by the systematic review, have prob-
809 lems with the analysis of compositional data.

810 In [50, 7] standard PCA is performed without applying log-ratio trans-
811 formations to compositional data. According to [52], this is likely to be
812 inadequate and in [53], a more appropriate method for performing PCA of
813 compositional data is shown.

814 The normality of compositional data is defined in [54]. It is stated that
815 it is convenient to transform compositional data using isometric log-ratio
816 transformation before the tests for normality can be applied. [47] violates
817 this requirement by applying the Shapiro-Wilk test for normality to untrans-
818 formed compositional data.

819 The Kruskal-Wallis test is used in [47] to analyze compositional data.
820 The test is used to evaluate the difference between three organization levels.
821 The Kruskal-Wallis test assumes that variables within each sample are in-
822 dependent [55]. However, values within compositional data vectors are not

Table 13: Goals for CV result analysis.

Purpose of the method	Name
Show the final priority of each prioritization item. Stakeholder priorities are combined into one value.	Chart or table of final priorities

detect stakeholder groups with similar priorities [10]	Bi-plot
show the relative number of issues that have received high, medium, or low priority [10]	Ternary plot
detect stakeholder groups with common priorities [10]	PCA
how the final value of prioritization item is constructed from priorities assigned by different stakeholder. This chart shows how much each stakeholder has contributed to the final value of prioritization item [51]	Distribution chart
the level of agreement between different stakeholders on value of particular prioritization item [51]	Disagreement chart
satisfaction of a stakeholder with the prioritization results by the calculating correlation between the final priorities and priorities assigned by a stakeholder [51]	Satisfaction chart
percentage of the divergence of the priorities assigned by a stakeholder [4]	average percentage of divergence
average percentage of items given a non-zero value [4]	
detect equal prioritization items (presented in this paper)	ECV

independent (as described in Section 2.4). Hence, we claim the Kruskal-Wallis test to be somewhat misused in [47].

7.3. Identifying Prioritization Items with Equal Priority Using ECV (RQ 3)

This section presents the results of applying ECV to the industrial and academic CV data as found through the systematic literature review. Six primary studies included the raw prioritization results in the paper itself or referenced online sources where the data was available. To collect the data from the remaining 34 papers, the authors of all papers were contacted.

First, the email addresses provided in the papers were used. If no answer was received authors were searched for using Google, Facebook and LinkedIn. Authors from 11 papers provided us with data to be used in the evaluation of ECV. However, due to confidentiality reasons we can not publish this data directly and instead urge interested parties to contact the authors directly.

In short, ECV was applied to 27 CV prioritization cases from 14 studies. In the cases of HCV, ECV was applied two times to the same data to test both compensated and uncompensated priorities. Equal items were detected in three prioritization cases. A summary of the results is presented in Table 14.

In [46] a prioritization of requirement understandability criteria is presented. One of the main findings of paper [46] is that from an academic

Table 14: Identified groups of equal items.

Paper identifier & Description	Type of CV	Pairs of equal items	Groups of equal items
Barney 2009 [41] Perceived priorities of software product investments in an ideal situation	comp. HCV	(A2, B4) (B4, B5) (B4, C1) (B5, B15) (B6, B7) (B7, B8) (B14, B15) (B14, B18) (B17, B18)	(A2, B4) (B4, C1) (B5, B15) (B6, B7) (B14, B15) (B17, B18)
	uncomp. HCV	(B4, B5) (B4, B8) (B5, B15) (B6, B7) (B7, B12) (B14, B15) (B14, B18) (B16, B17) (B12, B13)	(B4, B5) (B5, B15) (B6, B7) (B14, B15) (B16, B17) (B12, B13)
Berander 2009 [17] Software requirements for course management system	uncomp. & comp. HCV	(3:2, 3:3)	(3:2, 3:3)
Svahnberg 2008 [46] The view of academia researchers on the requirements understandability criteria	CV	(Development, Verification & Validation) (Development, Product Planning 1)	(Development, Product Planning 1)

viewpoint Development and Verification and Validation are more important than other criteria. ECV adds new knowledge to these results. It shows that Development and Verification and Validation are equally important, i.e. it is not true that either one of the criteria is more important.

A prioritization of software requirements for an academic course management system is presented in [17]. ECV detected that two features—Assignment Submission and Assignment Feedback—have the same priority. If the system is developed in several releases Assignment Submission and Assignment Feedback features can be freely interchanged between the releases and, hence, in this way ECV simplifies release planning.

In [41] software product investments are prioritized with HCV. The results of ECV was different for uncompensated and compensated HCV. When compensated HCV was used ECV detected equal items that belonged to different high level prioritization groups (A , B and C), indicating that ECV provided a more fine-grained view. In the case of uncompensated HCV, on the other hand, all equal items belonged to one high level prioritization group (group B).

8. Discussion and Conclusions

This section discusses the results of the systematic review and evaluation of ECV conducted as part of this study.

CV has been applied in various areas, but most frequently in requirements prioritization and release planning, and quite often also as part of research methodologies. A large part of the studies have been conducted in Sweden, at Ericsson AB. One can see a slight increase in the interest in CV. During the last five years there have been more studies that use CV than between, say, year 2000–2005.

Overall, studies that use CV or analyze the results of CV have a high quality in terms of correctness of research process and study realism. However, very few studies present prioritization of more than 30 items and the availability of research data is somewhat limited. In our particular case we were able to obtain data from 43% of the primary studies.

8.1. Implications for Practitioners

The results of this study provide decision support for industry practitioners. We believe that a collection of state of the practice studies help the adoption of CV prioritization method. (Top studies are summarized in Table 12.) In addition, a set of CV analysis methods enables comprehensive understanding of the prioritization results. (The analysis methods are

presented in Table 13.) One of the most common goals of CV analysis is to display of the prioritization results and, thus, to show the difference between several prioritization perspectives.

Additionally, we present ECV—a novel method for CV analysis. Prioritization often results in the assignment of similar priorities to several prioritization items. CV results contain both ‘real priorities’ and random errors. Due to random errors, equal prioritization items may receive different priorities. ECV identifies such items. It allows stakeholders to disregard the random part of the CV results. Thus, ECV simplifies the understanding of the prioritization results.

ECV identifies prioritization items with similar priority and tests whether these items can be considered equal. In this case, ECV can be used in software release planning. For example, let us suppose that a set of software requirements are prioritized with regard to the implementation costs. First of all, ECV can then detect items with equal cost. Second, the equal items can be freely swapped between the releases. Finally, the decision to allocate a requirement to a particular release can be made based on another criteria, such as risk or business value.

ECV has been successfully applied on a considerable amount of CV data and, additionally, has also detected equal items in different groups of HCV hierarchies.

8.2. *Implications for Academia*

In the systematic review 36% of papers were revealed by the snowball sampling. That is a considerable amount. Several studies do not mention the name of the prioritization method (i.e. cumulative voting or hundred dollar test). Others are not available through selected databases because they are conference publications or theses. It shows, in our opinion, that snowball sampling ought to be used in all systematic literature reviews.

CV results are a special type of data—compositional data. Standard statistical analysis methods that assume the independence of the samples cannot be applied to CV results. In [56] methods for the analysis of compositional data have been presented. The systematic review conducted as a part of this study revealed that 22 studies analyze CV results; yet, only one study uses compositional data analysis methods, i.e. [10]. None of the studies, including [10], present methods for detecting items with equal priority in CV results. Hence, ECV is, in this respect, a unique method.

The small use of compositional data analysis is really not surprising, since literature describing CV does not state that the results are compositional data. Standard statistical analysis methods may produce useful results for

919 compositional data. However, there are cases when they are misleading or
920 even faulty. Section 7.2.1 contains evidence of inappropriate use of statistical
921 methods by several papers.

922 This study has collected a set of compositional data analysis methods for
923 CV analysis (see Table 13). We believe that this could help researchers to
924 improve the analysis of CV results with appropriate methods.

925 Since CV is associated with compositional data, it might be tempting to
926 choose another requirements prioritization method. However, it would not
927 solve the problem *per se*, because any ratio scale prioritization, for instance
928 AHP, contains compositional data.

929 The principal implications for the academia are mainly the following:

- 930 1. All systematic literature reviews should include snowball sampling.
- 931 2. Researchers can improve their statistical analysis of CV results using
932 compositional data analysis methods collected and developed by this
933 study.
- 934 3. When CV or any other ratio scale prioritization method is taught,
935 compositional data analysis should also be presented as part of the
936 solution.

937 8.3. *Validity Threats*

938 The validity of the systematic review is mainly limited by the chosen
939 databases, the design of the review, and human judgement in study selection
940 and data extraction.

941 To mitigate the threats we use the most popular databases in the field
942 of software engineering. In the beginning of the systematic review a re-
943 view protocol was developed, peer-reviewed, and revised. Search strategy
944 was validated against a set of previously known papers obtained from other
945 researchers. One of many terms used to name cumulative voting is ‘\$100
946 method’. We were not able to search for this term because non of the cho-
947 sen databases support search for special characters like ‘\$’ and the search
948 string ‘100 method’ yields hundreds of thousands of results. To increase the
949 likelihood of discovering relevant studies snowball sampling was extensively
950 used.

951 To increase the validity of study selection, all included studies and 20
952 randomly selected excluded studies were examined by two researchers. There
953 were no disagreement on the inclusion/exclusion of the studies.

954 The large number of studies identified by snowball sampling (15 out of
955 40 studies) may be caused by faulty design or by faulty execution of the
956 search in the databases. There are several reasons why the studies revealed

957 by snowball sampling are not revealed by the search in databases. Reason
958 for each study is given in Table Appendix A.2. Based on these reasons we
959 argue that snowball sampling does not indicate any problems with the design
960 of the search in the databases.

961 Four studies were not found because they were not available through
962 databases used in this systematic review. Out of them one is a master
963 thesis, two are conference publications and one is a publication in the area
964 of forestry. Seven studies do not mention the name of the prioritization
965 method (i.e. hundred dollar method or cumulative voting). Only phrases
966 like “distribution of a predefined amount of fictitious money (\$100,000) over
967 the items to be prioritized” or “1,000 points” allowed us to identify that CV
968 was indeed used. One paper used a previously unknown name for CV, i.e.
969 the 100-point technique.

970 The quality of the data extraction and quality evaluation was validated
971 using inter-rater agreement analysis. In our case, 10% of the studies were
972 rated by two researchers and Krippendorff’s alpha was calculated. The agree-
973 ment for the data extraction results was 0.86 and the agreement for the
974 quality evaluation was 0.73 (indicating a credible level of quality).

975 There are two main validity threats with ECV itself. First, ECV may not
976 detect prioritization items with equal priority. Second, ECV may produce a
977 false positive result. There may be a real difference between items that ECV
978 claims as being equal.

979 To mitigate the first threat ECV was applied on artificially created test
980 data with and without items with similar priority. ECV worked correctly in
981 both cases.

982 To mitigate the second threat we visually inspected the results of the
983 application of ECV on the real world data from the primary studies. We
984 concluded that items identified by ECV can be considered equal.

985 CV results used in the evaluation of ECV were tested for normality. The
986 tests indicated that CV results do not have multivariate normal distribution.
987 Therefore, the design of ECV was based on a non-parametric statistical test.

988 8.4. Future Research

989 There are very few studies that apply CV on prioritization sets of more
990 than 30 items. However, in requirements engineering, industry practitioners
991 need to prioritize much larger numbers of software requirements. Therefore,
992 the state of art could benefit from the application of CV and HCV to large
993 prioritization sets.

994 The proposed method, ECV, has now been evaluated on existing research
995 data. To further evaluate the ECV, it could be applied in direct industry

996 practice and in prioritization cases with a larger number of prioritization
 997 items. Additionally, compositional data analysis methods, as the ones iden-
 998 tified by this paper, should be tried with other prioritization methods that
 999 produce ratio scale results.

1000 8.5. Conclusions

1001 CV prioritization results are special type of data – compositional data.
 1002 Any analysis of CV results must take into account the compositional nature
 1003 of the CV results.

1004 This study presents a systematic literature review of the empirical use
 1005 of CV. CV has been applied in various areas, but most frequently in re-
 1006 quirements prioritization and release planning. The review has resulted in
 1007 a collection of state of the practice studies and CV result analysis methods.
 1008 We believe that it can help the adoption of CV prioritization method.

1009 In our case, snowball sampling was performed as a part of the review.
 1010 Since it revealed 36% out of all primary studies, we believe that in future
 1011 snowball sampling should be used in all systematic reviews.

1012 Additionally, we present ECV—a novel method for CV analysis. As
 1013 suggested by our evaluation, ECV is able to detect prioritization items with
 1014 equal priority (i.e. items that have insignificant difference in priority). The
 1015 evaluation of ECV was based on the data obtained from the authors of the
 1016 primary studies.

1309 Appendix A. Primary Studies

1310 Appendix A.1. Primary studies found during search in databases.

1311	Title		Reference
	Prioritizing countermeasures through the countermeasure method for software security (CM-Sec)		Baca 2010 [57]
	The relative importance of aspects of intellectual capital for software companies		Barney 2009 [40]
	Software product quality: Ensuring a common goal		Barney 2009 [8]
	Balancing software product investments		Barney 2009 [41]
	Hierarchical cumulative voting (HCV) prioritization of requirements in hierarchies		Berander 2006 [4]
	A goal question metric based approach for efficient measurement framework definition		Berander 2006 [30]
	Evaluating two ways of calculating priorities in requirements hierarchies: An experiment on hierarchical cumulative voting		Berander 2009 [17]
	Election systems and voter turnout: Experiments in the United States		Bowler 2001 [58]
	A low information theory of ballot position effect		Brockington 2003 [59]
	Prioritization of issues and requirements by cumulative Voting: A compositional data analysis framework		Chatzipetrou 2010 [10]
	A comparison of cumulative voting and generalized plurality voting		Cooper 2010 [60]
	Challenges with software verification and validation activities in the space industry		Feldt 2010 [45]
	Investigating impact of business risk on requirements selection decisions		Fogelstrom 2009 [61]
	Choosing the right prioritization method		Hatton 2008 [62]
	Early prioritization of goals		Hatton 2007 [63]
	Rigorous support for flexible planning of product releases: A stakeholder-centric approach and its initial evaluation		Heikkilä 2010 [64]
	Voting methods in strategic forest planning: Experiences from Metsähallitus		Hiltunen 2008 [13]
	Empirical extension of a classification framework for addressing consistency in model based development		Kuzniarz 2010 [48]
	Evaluation of the multi-criteria approval method for timber-harvesting group decision support		Laukkanen 2005 [43]
	A practitioner's guide to light weight software process assessment and improvement planning		Pettersson 2008 [7]
	An empirical study on views of importance of change impact analysis issues		Rovegard 2008 [49]
	An industrial case study on the choice between language customization mechanisms		Staron 2006 [65]
	Perspectives on requirements understandability—For whom does the teacher's bell toll?		Svahnberg 2008 [46]
	A study on the importance of order in requirements prioritization		Svahnberg 2009 [16]
	A structured goal based measurement framework enabling traceability and prioritization		Touseef 2010 [66]

1312 *Appendix A.2. Primary studies revealed by snowball sampling.*

Reference	Title	Reason why the paper is not revealed by the search in databases
Ahl 2005 [3]	An experimental comparison of five prioritization methods	Selected databases does not contain the paper, master thesis at BTH
Barney 2008 [42]	A product management challenge: Creating software product value through requirements selection	Prioritization method name not mentioned, phrase "1,000 points" used instead.
Berander 2004 [67]	Differences in views between development roles in software process improvement—A quantitative comparison	Prioritization method name not mentioned, phrase "100 points" used instead.
Berander 2004 [68]	Using students as subjects in requirements prioritization	Unknown CV name: 100-point technique
Berander 2003 [69]	Identification of key factors in software process management: A case study	Prioritization method name not mentioned, phrase "100 points" used instead.
Cole 1990 [70]	Cumulative voting in a municipal election: A note on voter reactions and electoral consequences	Study published before year 2001.
Hu 2006 [44]	Adding value to software requirements: An empirical study in the chinese software industry	Prioritization method name not mentioned, phrase "1,000 points" used instead.
Jonsson 2005 [9]	A study on prioritization of impact analysis issues: A comparison between perspectives	Selected databases does not contain the paper.
Jonsson 2005 [47]	Understanding impact analysis: An empirical study to capture knowledge on different organizational levels	Selected databases does not contain the paper.
Kuklinski 1973 [71]	Cumulative and plurality voting: An analysis of Illinois' unique electoral system	Study published before year 2001.
Laukkanen 2004 [72]	Applying voting theory in participatory decision support for sustainable timber harvesting	Selected databases does not contain the paper.
Regnell 2001 [31]	An industrial case study on distributed prioritization in market-driven requirements engineering for packaged software	Prioritization method name not mentioned: "distribution of a predefined amount of fictitious money (\$100,000) over the items to be prioritized."
Regnell 2000 [51]	Visualization of agreement and satisfaction in distributed prioritization of market requirements	Prioritization method name not mentioned: "distribution of a predefined amount of fictitious money (\$100,000) over the items to be prioritized."
Wohlin 2006 [73]	Game theory and cumulative voting in Illinois: 1902–1954	Study published before year 2001.
Wohlin 2006 [50]	Criteria for selecting software requirements to create product value: An industrial empirical study	Prioritization method name not mentioned: "The subjects had 1,000 points to spend among the 13 criteria."

Appendix B. CV Result Analysis Methods

	Paper																					
	Svalenberg2008	Svalenberg2009	Starr2006	Petersson2008	Wohlitz2006	Laukkonen2005a	Hu2006	Jonsson2005a	Kuzmar2010	Rowgard2008	Bernard2006a	Bernard2004a	Bernard2006	Feldt2010	Barney2009b	Barney2008	Barney2009a	Barney2009	Jonsson2005	Chatzipetrou2010	Reguel2001	Reguel2000
Analysis method																						
Table that shows final priorities	x			x												x						
Chart that shows final priorities	x			x	x	x																
Table of top-5 prioritization items																						
min , max , \bar{x} , \bar{x} and σ of priorities assigned by different stakeholders									x	x												
Bar chart of prioritization results showing \bar{x} priority and σ of priorities									x	x												
Pearson correlation coefficient		x										x										
Nemenyi-Damico-Wolfe-Dunn														x								
Spearman's r															x							
Kruskal-Wallis								x								x		x				
Wilcoxon								x														
Correlation matrix		x														x		x				
Chart for comparing priorities from two perspectives, priorities are points in two dimensional plane, x - and y -axis represent two different perspectives										x									x			
Difference between priorities assigned by each two stakeholders using χ^2 -statistic										x												
Median ranks		x																				
CV results converted to priority ranks		x											x						x			
PCA				x	x															x		
Percentage of divergence of priorities assigned by a stakeholder											x											
Average percentage of items given non-zero value											x											
Distribution chart																					x	x
Disagreement chart				x																	x	x
Satisfaction chart			x																		x	x
Bi-plot																					x	
Ternary plot																					x	

Appendix C. Quality Evaluation Checklist

Item	Question or Description of the Item	Rating
1. Background, introduction	Introduce research area	
2. Problem statement, purpose	What is the problem [35]? Where does it occur [35]? Who has observed it [35]? Why is it important to be solved [35]?	
3. Context, independent variables (aka. environment, setting)	Study location, time constraints, application domain, organization, tools, market, process (e.g. software development methodology), size of project, product that is being developed	
4. Related work	Other existing work, alternative technologies, solutions, and studies	
5. Goals and Hypotheses	Null hypothesis and one or more alternative hypotheses for each goal	
6. Research questions		
7. Design, Research methods		
7.1. Design	Description of each step of the study	
7.2. Control group	If there is a control group, are participants similar to the treatment group participants in terms of variables that may affect study outcomes[29]?	
7.3. Randomization	Random selection of participants and objects Random assignment of treatment and objects to participants Random order of treatments in case of paired design. If each participant is assigned two treatments A and B, then part of participants perform A first and the other part start with B	
7.4. Blocking	Group participants of the study into homogeneous groups called blocks (e.g. students in one course, database developers in one company) and implement the study design within each block independently. The idea is that variability of independent variables (e.g. experience and knowledge of subjects) is smaller within a group. That helps measuring changes in dependent variables [32].	
7.5. Balancing	Equal number of subjects should be assigned to each treatment [32].	
7.6. Blinding	Automated assignment of treatments to subjects [32] Automated distribution of study materials to subjects [32] Persons who grade the task results should not know which treatment was used [32] Analyst should not know which treatment group is which [32] Automated data collection from subjects [32]	
8. Subjects (participants)		
8.1. Population		
8.2. Sampling	How sampling is performed? What subjects are included and excluded? [29] What is the type of the sampling (e.g. convenience, random)? Is the sample(selected participants) representative of the population?	
8.3. "Drop outs" and response rate	Are reasons given for refusal to participate[29]?	
8.4. Subject motivation	E.g. material benefits, course credits for students, etc.	
9. Objects	E.g. documents and other artifacts	
10. Measures, Data collection procedures	Who, when, and how to measure [29]? How is the measurement supported? Is it automated [29]? Are the measures used in the study the most relevant ones for answering the research questions [29]?	
11. Analysis procedure		
11.1. Data description	Do the numbers add up across different tables and subgroups [29]?	
11.2. Data types (continuous, ordinal, categorical)		
11.3. Scoring systems		
11.4. Data set reduction, outliers		
11.5. Statistical methods	Are the assumptions of statistical methods met? What statistical programs are used?	
11.6. Statistical significance	If statistical tests are used to determine differences, is the actual p-value given [29]? If the study is concerned with differences among groups, are confidence limits given describing the magnitude of any observed differences [29]?	
12. Validity threats	Threats, implications of the threats, and threat mitigation	
12.1. Side-effects during study execution	Deviations from the plan, solutions for the deviations	
13. Most important findings	Are all study questions answered [29]? Are negative findings presented [29]?	
14. Industry impact, inference, generalization	What implications does the report have for practice [29]? How and where the results can be used? Limitations under which findings are relevant [35]?	
15. Future work
