## Abstract

**Context.** Prioritization is essential part of requirements engineering, software release planning and many other software engineering disciplines. Cumulative Voting (CV) is known as relatively simple method for prioritizing requirements on a ratio scale. Historically, CV has been applied in decision making in government elections, corporate governance, and forestry. CV prioritization results are special type of data – compositional data.

**Objectives.** The purpose of this study is to aid decision making by collecting knowledge on the empirical use of CV and developing a method for detecting prioritization items with equal priority.

**Methods.** We present a systematic literature review of CV and CV result analysis methods. The review is based on search in electronic databases and snowball sampling of the primary studies. Relevant studies are selected based on titles, abstracts, and full text inspection. Additionally, we propose Equality of Cumulative Votes (ECV) – a CV result analysis method that identifies prioritization items with equal priority.

**Results.** CV has been used in not only in requirements prioritization and release planning but also in software process improvement, change impact analysis, model driven software development, etc. The review has resulted in a collection of state of the practice studies and CV result analysis methods. ECV has been applied to 27 prioritization cases from 14 studies and has identified nine groups of equal items in three studies.

**Conclusions.** We believe that collected studies and CV result analysis methods can help the adoption of CV prioritization method. The evaluation of ECV indicates that it is able to detect prioritization items with equal priority.

## 1. Introduction

Software products are becoming larger and more complex. Each product is usually affected by a large number of factors such as product functional requirements, quality attributes, or software process improvement issues. Since time, funding, and resources are limited, it is seldom possible or efficient to fully address all the factors. Therefore, the level of attention to a particular factor should be decided according to its importance (i.e. business value), cost, risk, volatility, dependencies between the factors and other criteria. These type of decisions are made by product stakeholders: users, clients, managers, sponsors, developers, and other persons associated with the product. In order to make decisions regarding a large number of factors it is highly advisable to prioritize the factors in a systematic way [1].

One of the prioritization methods used in software engineering is Cumulative Voting (CV) [2]. The main advantage of CV is that it is relatively simple and fast, yet produces priorities in ratio scale [1, 3]. This allows us not only to determine what prioritization items are more important but also how much more important they are. (Ratio scale prioritization is particularly important in software release planning and cost-value analysis [4, 5].)

Prioritization is usually performed by multiple stakeholders where individual priorities are combined into a single priority list. Each stakeholder's preferences may have different weight in the final priority. Such prioritization provides more information than just the priorities of factors. It may be useful to analyze the results of the prioritization to assess disagreement between stakeholders, measure stakeholder satisfaction with the results or find distinct groups of stakeholders.

The purpose of this study is to help industry practitioners and academia researchers in adopting, using and developing CV, while the importance of prioritization in software engineering and the prospectiveness of CV constitutes a need to do further research in this area.

This study presents a systematic literature review of the empirical use of CV and CV result analysis methods. A new method for CV result analysis, called Equality of Cumulative Votes (ECV), is proposed. The method identifies prioritization items with *equal* priority. ECV is evaluated using a considerable amount of data, which was obtained from the primary studies identified by the systematic review (through the kindness of the authors of said studies).

The remainder of this paper is structured as follows. The background is presented in Section 2. Section 3 describes related studies. In Section 4 research questions and methods are presented. The design of the systematic

40 review is presented in Section 5 and ECV is presented in Section 6. Section 7  
41 presents the results of the study and Section 8 is a discussion section.

## 42 **2. Background**

43 This section presents definitions and places this study in a context. In the  
44 coming sections we will cover: a description of software requirements priori-  
45 tization methods; examples of CV result analysis methods; and a description  
46 of compositional data analysis and CV.

### 47 *2.1. Prioritization Methods*

48 Some of the most popular prioritization methods are the analytical hi-  
49 erarchy process (AHP), cumulative voting (CV), ranking, numerical assign-  
50 ment, top-ten, the planning game, minimal spanning tree, bubble sort and  
51 binary search tree [1, 6]. Ranking and numerical assignment methods per-  
52 form prioritization on an ordinal scale. AHP and CV are, on the one hand,  
53 considered to be harder to use and also more time consuming compared to  
54 other methods but, on the other hand, produce priorities in ratio scale.

55 Prioritization can be used not just to decide which factors to address, but  
56 also to determine the order in which they need to be handled. In market-  
57 driven software development a small part of a very large number of require-  
58 ments need to be selected and divided into several releases to maximize return  
59 on investment. While in bespoke requirements, focusing on early delivery of  
60 value can help reduce the risk of project cancellation.

61 Ratio scale priorities have several advantages over ordinal scale priori-  
62 ties. Ratio scale shows not just the order of items but also relative distance  
63 between them. This enables the priority of a group of items to be calculated  
64 by summing up the priorities of individual items [4]. It is possible to say  
65 that one item or set of items has higher priority than another set of items.  
66 Supposing stakeholders have to choose between several low priority items  
67 and one item with higher priority; with ordinal scale, the item with high-  
68 est priority will always be selected first. However, if priorities are given on  
69 a ratio scale, it is possible that lower priority items will be selected if their  
70 cumulative priority is higher. Knowing the relative importance of sets of pri-  
71 oritization items helps in software release planning. Ratio scale allows the  
72 combining of multiple priority factors by calculating ratios between them.  
73 One example of this is the cost-value ratio that shows which requirements  
74 give more value for less money [5].

## 75 2.2. Prioritization Result Analysis

76 Different studies use and analyze CV in different ways. Disagreement  
77 between stakeholders happens when two or more stakeholders have assigned  
78 a different priority to one prioritization item. If the level of disagreement is  
79 high it may indicate potential conflicts between stakeholders. Such conflicts  
80 may be of technical character, as well as social or cultural.

81 The satisfaction a stakeholder has with the final prioritization results is  
82 determined by the difference between the results and the individual priorities  
83 of the stakeholder. A smaller level of difference leads to higher satisfaction.  
84 In the end, stakeholder satisfaction is important because it is necessary to  
85 achieve stakeholder commitment.

86 In some cases a part of stakeholders may form a group of some kind and,  
87 therefore, prioritize requirements similarly. It may be useful to detect whether  
88 a group of stakeholders has different preferences than all other stakeholders.  
89 As an example, in [7] domain experts, technical experts, managers, project  
90 managers, testers, and developers use CV to prioritize software process im-  
91 provement issues and the CV results are analysed using disagreement charts  
92 and satisfaction charts. Finally, principal component analysis (PCA) is used  
93 to identify distinct groups of stakeholders.

94 The same items can be prioritized by the same stakeholders multiple  
95 times from different perspectives. In this case it is useful to determine corre-  
96 lation between the priorities in different perspectives to assess the differences  
97 between the perspectives. As an example, in [8] CV is used by developers,  
98 testers, and managers to prioritize quality attributes. The same quality at-  
99 tributes are prioritized from two perspectives: the perceived situation today  
100 and the perceived ideal situation. Correlation between the two perspectives  
101 is evaluated using the Spearman rank correlation matrix. This allows an  
102 analysis of how well the company balances the priorities of software quality  
103 attributes.

104 In [9] change impact issues are prioritized by developers, testers, man-  
105 agers, and system architects. The prioritization is done with respect to three  
106 perspectives: strategic, tactical, and operative. In order to determine corre-  
107 lation between the perspectives, CV results are analysed using the Kruskal-  
108 Wallis test. In [10] the results of [9] are further analysed using PCA, bi-plot,  
109 and ternary plot. In this case, PCA is used to find correlated issues, bi-  
110 plot shows variance, correlation, difference between the priorities of issues,  
111 and the viewpoints of stakeholders, while ternary plots are used to show the  
112 relative number of issues that received high, medium, and low priority.

113 As can be seen above, from the examples given, prioritization has been  
114 performed with various stakeholders, using different perspectives and, in the

115 end, also analysed using various techniques. We will next describe in more  
116 detail one of the more common methods to manage prioritization issues —  
117 cumulative voting — which has been used in software engineering for some  
118 time, but has its roots in corporate governance and biology.

### 119 *2.3. Cumulative Voting*

120 CV is a prioritization method for prioritizing a list of items [2]. CV has  
121 many synonyms in literature: hundred dollar method, hundred dollar test,  
122 hundred point method, 100\$ dollar method, 100\$ dollar test, 100\$ point  
123 method. Before being applied in software engineering CV was used for polit-  
124 ical elections [11] and corporate governance [12]. CV has also been applied  
125 in e.g. decision making in forestry [13], voting in social networks [14] and in  
126 computer algorithms for consensus clustering [15] (as a method for combining  
127 the results of different clustering algorithms).

128 In CV a stakeholder is given 100 points, imaginary dollars or units of  
129 percentages that can be spent on the prioritization items. In the simplest  
130 case, the stakeholder can spend any amount of points on any number of items  
131 as long as the total amount adds up to 100. The more points assigned to an  
132 item, the higher the priority of the item (and implicitly, the lower priority  
133 to the other items). The stakeholder may spend all the points on just one  
134 item or distribute them among all or some of the items. Once again, this is  
135 the simplest case; other variants exist, which we will see next.

136 Often prioritization is done by more than one stakeholder. The final  
137 priority of an item can be calculated by adding up the points each stakeholder  
138 has spent on it. Sometimes the vote of some stakeholders may be more  
139 important than the votes of others. For example, a manager may be more  
140 influential and shareholders may have different amount of shares. In such  
141 a case the priorities of each stakeholder may be multiplied by an individual  
142 coefficient or a different amount of points for prioritization.

143 Worth mentioning in this context is that it is advisable to randomize the  
144 order of items in a prioritization list. This is necessary in order to minimize  
145 the effect of order on the prioritization results, which has shown to have an  
146 effect [16].

#### 147 *2.3.1. Benefits and Drawbacks of Cumulative Voting*

148 Compared to analytical hierarchy process (AHP), CV is faster and easier  
149 to learn and use [1, 3]. AHP benefits from consistency check, but CV does  
150 not require this because all prioritization items are evaluated simultaneously  
151 [3].

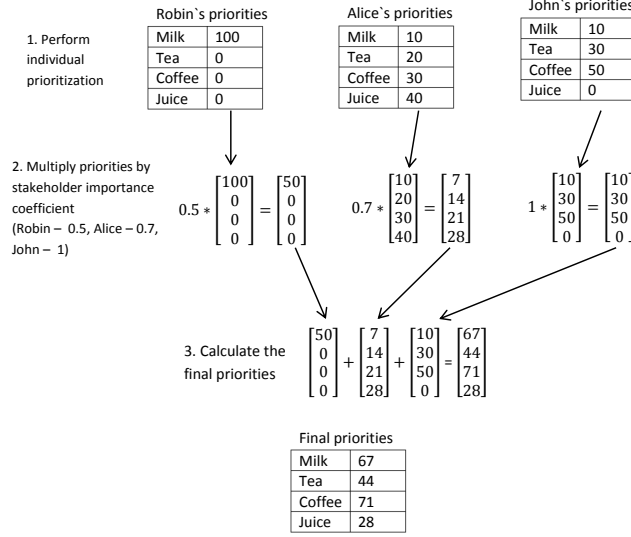

Figure 1: Example of CV with several stakeholders.

152 There are, however, a few problems with CV. First of all, it cannot be  
 153 repeated for the same stakeholders and prioritization items due to stake-  
 154 holder bias [2] (c.f. Section 2.3.4). Secondly, CV becomes more difficult if  
 155 the number of prioritization items increases [17].

### 156 2.3.2. Example of Cumulative Voting with Several Stakeholders

157 Let us give an example of CV with several stakeholders. Suppose Robin,  
 158 Alice, and John are three friends who want to buy some beverages in a store.  
 159 They have different preferences but do not want to buy too many drinks.  
 160 Therefore, they decide to use CV to decide what to buy. Each of the friends  
 161 distributes 100 points between four items: milk, tea, coffee, and juice (Step  
 162 1 in Figure 1). Each of them will spend a different amount of money on  
 163 the purchase, hence, their priorities are multiplied by different coefficients  
 164 (Step 2 and the stakeholder importance coefficient in Figure 1). The final  
 165 beverage priorities are calculated by summing up the weighted priorities of  
 166 stakeholders (Step 3 in Figure 1).

### 167 2.3.3. Stakeholder Bias

168 Prioritization using CV may be biased if a stakeholder knows the pref-  
 169 erences of other stakeholders. She may manipulate the results by spending

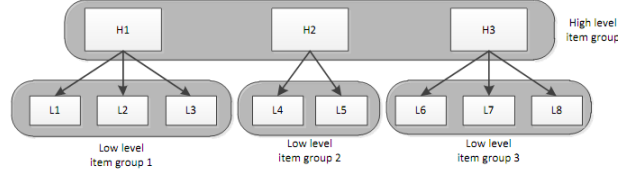

Figure 2: Example of prioritization item hierarchy.

more points on items that are important to her but not the other stakeholders. On the one hand, stakeholder bias makes it unreasonable to repeat CV with the same prioritization items and stakeholders. On the other hand, this property of CV may be useful in giving more power to important minority stakeholders, such as security experts or software testers. Suppose the same software requirements are prioritized for a second time using CV. A developer might know that all vital functionality is selected by other stakeholders, but his toy feature is left out. In effect, the developer could spend all his points on this feature to put it in the next release.

Stakeholder bias may be mitigated by setting a maximum priority that can be assigned to an item. This way each stakeholder is forced to distribute the money between several prioritization items [4].

Another bias is that people in general tend to assign round priority values. This is likely caused by lack of objective judgement criteria. Either way it seems to be a problem not acknowledged by many since all prioritization is largely based on expert opinion.

#### 2.3.4. Scalability of Cumulative Voting, Hierarchical Cumulative Voting

The standard CV approach has a low scalability. If the number of prioritization items is high, stakeholders may lose sight of the bigger picture and assign priorities to a limited number of items. One, unsophisticated, solution to the problem is to provide more points for prioritization (1,000 or 10,000 instead of 100); however, one could take another approach.

When the number of prioritization items is high they can usually be grouped hierarchically by forming a tree structure (Figure 2) and, thus, parent-child dependencies will exist between many items.

In [4] the authors propose a method for prioritizing hierarchically structured items called Hierarchical Cumulative Voting (HCV). It may be seen as combination of the hierarchical part of the Analytical Hierarchy Process (AHP) [1, 18] and the CV prioritization method. Since items are prioritized in smaller sets, stakeholders do not lose sight of the bigger picture during

200 prioritization, and the prioritization of a large number of requirements is  
201 considered easier.

### 202 2.3.5. *Compensation Factors*

203 HCV deals with the problem of prioritization scalability but it comes at  
204 a cost. Low level item groups may consist of different numbers of items, but  
205 the number of points spent on each group is the same, i.e. in a small-sized  
206 group, the same amount of points is distributed among fewer items. Hence,  
207 items in smaller groups are statistically more likely to have a higher priority,  
208 on average, compared to items in larger groups. To balance this difference  
209 each low level prioritization item can be multiplied by a compensation factor  
210 [4].

211 As an example, suppose an item ( $A$ ) in a group of 10 items is assigned  
212 60 points. Hence,  $A$  will receive 600 compensated points. In this case it is  
213 impossible for any item in a group smaller than 6 items to compete with  $A$ .  
214 Even if item ( $B$ ) in a group of 5 is assigned the maximum number of points  
215 (100), the maximum compensated priority value  $B$  can receive is 500.

216 In [17] the authors suggest that compensated prioritization is more fa-  
217 vorable compared to uncompensated. But neither compensated nor uncom-  
218 pensated prioritization is perfect and, as a general rule, it is better to keep  
219 the size of prioritization item groups similar.

### 220 2.3.6. *HCV Execution*

221 According to [4], HCV is conducted with the following steps (Steps 4–5  
222 are optional):

- 223 1. Construct hierarchy. Prioritization items need to be divided into one  
224 high and several low level item groups. Each low level item group is  
225 child to exactly one high level item. And each high level item has  
226 one low level item group. One low level item may belong to several  
227 item groups. Even if part of the items are not logically connected they  
228 can be grouped separately and assigned a fake parent item, e.g. ‘misc.  
229 items’. HCV does not, as far as we know, provide any directions on  
230 creating a requirements hierarchy.
- 231 2. Each high and low level item group is prioritized separately using CV.  
232 The stakeholder may prioritize all item groups at once or one by one.  
233 But it should be possible to prioritize groups in any order and repeat-  
234 edly, because the stakeholder might learn more about the items while  
235 performing the prioritization.  
236 In particular the stakeholder is likely to learn more about a high level  
237 item when prioritizing its low level item group [19]. Some stakeholders

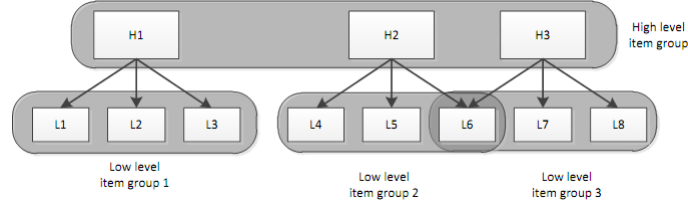

Figure 3: Overlapping prioritization item hierarchy example.

- may prioritize only part of the groups and each group may be prioritized by different stakeholders.
3. The priority of each low level item is normalized by dividing it with the sum of all low level priorities of each item in all groups.
  4. The final priority of each low level item is calculated by multiplying it with the priority of its parent high level item.
  5. Then apply the compensation factor to all low level requirements as described in Section 2.3.5.
  6. Finally, when multiple stakeholders have performed the prioritization, priorities of low level items are combined as in standard CV.

It is possible that one low level item is child of more than one high level requirement and, thus, belongs to two or more low level requirement groups (see Figure 3). Such requirements participate in the standard HCV prioritization process and are prioritized two or more times with each group they belong to. At the end of the prioritization they receive several priority values. These values can be summed together to form the final priority of the item. (This is done because the item adds value to both parts of hierarchy.)

#### 2.3.7. Example of Hierarchical Cumulative Voting

In this section we will give a short example of HCV. Suppose six requirements for a mobile phone operating system need to be prioritized: ‘reminder alarm’, ‘specify repeated event’, ‘hide contact’, ‘add picture to phonebook’, ‘search contact’, ‘make video call’. Three high level requirements can be identified: ‘Calendar’, ‘Phonebook’, ‘Call’. The low level requirements are then grouped as sub-requirements of high level requirements as shown in Figure 4. The ‘Search contact’ requirement is a sub-requirement and has two parent requirements: ‘Phonebook’ and ‘Call’. The computation of the final priorities of requirements is shown in Table 1.

After requirements are grouped, and a hierarchy is defined, each group of requirements are then prioritized using CV. The final priority of a low level

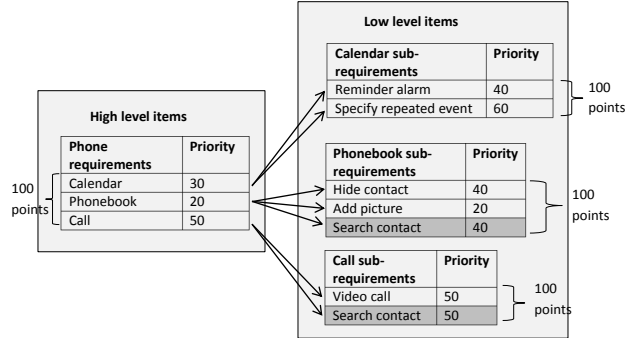

Figure 4: Example of hierarchical cumulative voting, requirement hierarchy

Table 1: Example of hierarchical cumulative voting.

Phone requirements	Compensation factor	Sub-requirements	Priority calculation	Final priority
Calendar	2	Reminder alarm	$40 \times 30 \times 2$	2400
Calendar	2	Specify repeated event	$60 \times 30 \times 2$	3600
Phonebook	3	Hide contact	$40 \times 20 \times 3$	1600
Phonebook	3	Add picture	$20 \times 20 \times 3$	800
Phonebook & Call	3 & 2	Search contact	$40 \times 20 \times 3 + 50 \times 50 \times 2$	7400
Call	2	Video call	$50 \times 50 \times 2$	2500

requirement is computed by multiplying the priority of the requirement with the priority of its parent high level requirement and the compensation factor. The compensation factor in this particular case is the number of elements in a group, two for the ‘calendar’ and ‘call’ sub-requirements and three for the ‘phonebook’ sub-requirement.

#### 2.4. Compositional Data Analysis

CV results can be seen as a special type of data, i.e. compositional data. Compositional data does not contain absolute values. It shows only the relative weight of a component in a whole. In [10] the authors propose the use of compositional data analysis for the statistical analysis of CV.

A compositional data item is a vector  $(x)$  of positive components with a constant sum  $k$ :

$$x = (X_1; X_2; \dots; X_n) \text{ where } x_i \geq 0 \text{ and } \sum_{j=1}^n x_j = k. \quad (1)$$

279 The property of the sum of the items being restricted is called the con-  
280 stant sum constraint. In CV, priorities assigned by a stakeholder to the  
281 items of a prioritization set is a compositional data vector with a constant  
282 sum of 100. The value of  $k$  (i.e. 100 in this case) is arbitrary and does not  
283 affect the analysis of the data because the information is contained in the  
284 ratios between the components of the vector. The vector can sum up to any  
285 number but still hold the same data, i.e. vectors (1, 2, 7) and (10, 20, 70) are  
286 in this case considered equivalent. This principle is called *scale invariance*.

287 Another property of compositional data items is *subcompositional coher-*  
288 *ence*. Consider that two compositions are analysed. One composition is a  
289 subcomposition of the other. *Subcompositional coherence* means that the re-  
290 sults of the analysis are the same for the common parts of the compositions  
291 [20]. This property is important for the analysis of HCV results. Statements  
292 that are made regarding each smaller group of prioritization items are also  
293 true for all items prioritized with HCV.

294 The priority of an item is relative to the priority of the other items in  
295 the set. Hence, the priority of an individual item is meaningless without  
296 context, i.e. the complete set of items. The same item may receive different  
297 priority when put in two different prioritization sets. If the item is put in a  
298 set of items with high priority it will receive a lower relative priority. This  
299 also holds true the other way around i.e. if the item is put in a set with low  
300 priority items its priority will be higher.

301 When doing analysis of compositional data one must take into account  
302 that compositional data special type of data and should be analysed differ-  
303 ently than ordinary data. Ordinary unconstrained variables are free to take  
304 any positive or negative values, whereas, compositional data values can only  
305 be positive and have a constrained maximum value. Moreover, components  
306 of compositional data vectors are not independent from each other. The fact  
307 that an item is assigned 70 priority points means that the next item can take  
308 only values between 0 and 30. Hence, there is a negative correlation between  
309 the items.

310 Standard parametric statistical tests require that data vectors have mul-  
311 tivariate normal distribution. Vector  $X = (X_1, X_2, \dots, X_n)$  is considered to  
312 have multivariate normal distribution if any linear combination of its parts  
313 is normally distributed, and linear combination is defined by:

$$Y = a_1X_1 + a_2X_2 + \dots + a_nX_n, \quad (2)$$

314 where  $Y$  is the product of lineal combination and  $a_i$  is any real number.  
315 Now, since the sum of priorities assigned in CV must add up to 100 (or any

316 other constant number) at least one linear combination of  $X$  is not normally  
 317 distributed because it always adds up to 100:

$$Y = 1 \cdot X_1 + 1 \cdot X_2 + \dots + 1 \cdot X_n = 100. \quad (3)$$

318 In our opinion, the above indicates, quite strongly, that CV results do  
 319 not follow a multivariate normal distribution and, hence, it follows that they  
 320 should be analysed using non-parametric statistical tests [21].

#### 321 2.4.1. Problem of Zeroes

322 Compositional data analysis requires that log-ratios between any com-  
 323 ponents in a vector can be computed. But computing a log-ratio with a  
 324 zero value is, in this case, meaningless. This is a problem since CV allows  
 325 stakeholders to assign zero priorities to some prioritization items (we would  
 326 even strongly argue that this is very common).

327 In compositional data there are two types of zeroes: essential and rounded.  
 328 Essential zeroes mean that a data component is not present. Rounded zeroes  
 329 mean that the component is present but its value is very low. We, as others  
 330 have before us, conjecture that zeroes in CV results are rounded because the  
 331 priority of an item is a completely abstract notion and the instrument for  
 332 measuring priority is human judgement [10].

333 Before compositional data analysis can be applied to CV results, we  
 334 should first remove zeroes in the data. One approach can be to forbid stake-  
 335 holders to assign zero priorities. This approach is used in e.g. [7]. But this  
 336 can add some unnecessary complexity to the prioritization process and, ex-  
 337 plicitly, delimits an expert's freedom. In [10] the authors propose the use  
 338 of a multiplicative replacement strategy (as defined in [22]) for CV result  
 339 analysis.

This method replaces rounded zeroes with small values using the expres-  
 sion

$$r_j = \begin{cases} \delta_j, & \text{if } x_j = 0, \\ (1 - \frac{\sum_{k|x_k=0} \delta_k}{c})x_j, & \text{if } x_j > 0, \end{cases} \quad (4)$$

340 where  $\delta_j$  is the imputed value and  $c$  is the constant sum constraint.  
 341 In order for the total sum of components to stay constant, the equation  
 342 subtracts some value from the items with a priority higher than zero. More  
 343 is subtracted from components with higher values than from components  
 344 with lower values (and the value of the imputed  $\delta_j$  is arbitrary).

#### 345 2.4.2. Isometric log-ratio transformation

346 In order to apply standard statistical methods to compositional data  
 347 it should be transformed to remove the inherent correlation of the values.  
 348 Compositional data analysis proposes special transformations that change  
 349 the compositional data values to unconstrained real values. One such trans-  
 350 formation is isometric log-ratio (*ilr*) transformation (as proposed by [21, 23]):

$$\begin{aligned} z &= (z_1, \dots, z_{D-1}), \\ z_i &= \sqrt{\frac{i}{i+1}} \log \frac{\sqrt[i]{\prod_{j=1}^i x_j}}{x_{i+1}} \text{ for } i = 1, \dots, D-1, \end{aligned} \quad (5)$$

351 where  $x$  is the vector that is being transformed and  $z$  is the vector that  
 352 is created. It should be noted that  $z$  is shorter than  $x$  by one element.

353 After compositional data vectors are transformed using zero replacement  
 354 and *ilr*, any standard statistical tests can be applied.

### 355 3. Related Work

356 A systematic review of requirements prioritization methods is presented  
 357 in [24]. The study focuses on prioritization method comparison and selects  
 358 eight relevant studies. Two of the studies use CV. These studies are also  
 359 revealed by the systematic literature review conducted as part of this study.  
 360 Khan [24] concludes that there is little research on requirements prioritization  
 361 and studies usually deal with a small number of requirements.

362 The systematic literature review presented in this paper does not reveal  
 363 any CV result analysis methods that allows to identify prioritization items  
 364 with equal priority. Thus, this problem is not addressed in any way.

### 365 4. Methodology

366 This section covers the research questions of this study and the methods  
 367 used to answer them.

#### 368 4.1. Selection of Research Methods

369 The main purpose of this study is to collect knowledge on the use of CV  
 370 in order to help software engineers and researchers in adopting it.

371 One way of collecting this knowledge is to conduct an empirical study. A  
 372 survey in a large number of software companies can be used to quantify the

level of adoption of CV in industry (similarly to the study by [25]), while a case study can be used to receive qualitative feedback on the use of CV [26].

Knowledge on the empirical use of CV can also be obtained from existing studies. This may be done by means of a systematic literature review. Several studies have used CV in industry as well as in academic settings. Nevertheless, there are no studies that provide an overview of the current state of the practice in this field (as reported by research studies). Therefore, before continuing with the refinement of CV and conducting new empirical studies (i.e. case study or experiment), a systematic literature review would be required.

This paper proposes a new method for CV result analysis, called Equality of Cumulative Votes (ECV). (ECV groups prioritization items into groups of items with similar priority.) As will be presented later, the systematic review did not reveal any methods that solve this problem; however, ECV needs to be evaluated and, hence, applied to CV results.

There are two options to obtain CV results in order to test ECV. One is to conduct a new empirical study. The second option is to collect CV results from existing studies. The latter approach also has the added benefit of trying to replicate the results from previous studies and, if the CV results from other studies are used, a larger amount of data can be obtained. Moreover, the generalizability of the evaluation increases when prioritization results from different sources and domains are used. On the other hand, the main benefit of conducting a separate empirical study is the possibility to control the conditions of CV.

In our study we evaluated ECV by obtaining data from previously conducted studies as found by the systematic literature review. In order to obtain the data, authors of relevant primary studies were contacted.

In short, this study consists of two parts: a systematic literature review (SLR) of CV and an evaluation of ECV based on the data from the primary studies found in the SLR.

#### *4.2. Research Questions*

The systematic review should focus on catching studies that empirically use CV. Information about place, time, scale, and domain of the studies should be collected and the results of the review will hopefully aid academic researchers by identifying paths for further investigation of CV. Hence, the first research question is:

**RQ 1.** What is the state of practice in empirical studies that use CV?

410 The level of trust in research results considering CV is determined by the  
411 quality of the studies that use CV, hence this study includes an evaluation  
412 of the quality of primary studies identified by the systematic review.

413 Next, a valuable aspect of decision making is the analysis of prioritization  
414 results. Thus, the second research question is:

415 **RQ 2.** What CV result analysis methods have been presented in papers as  
416 identified by RQ 1?

417 Finally, the evaluation of ECV answers the third research question:

418 **RQ 3.** Is ECV capable of identifying prioritization items with equal prior-  
419 ity?

## 420 5. Systematic Literature Review

421 This section presents the design of the systematic literature review. For  
422 the results of the execution please see Section 7.1 and 7.2.

423 Table 2 presents an overview of activities performed during the system-  
424 atic literature review. The review protocol was developed by one researcher  
425 and evaluated by another researcher. Studies were searched for in two itera-  
426 tions. The first search was performed by using databases. The second search  
427 was performed using snowball sampling [27] (snowball sampling examines the  
428 references of primary studies revealed by the first search). References that  
429 are relevant to the review, i.e. they pass the selection criteria, are then added  
430 to the set of primary studies.

431 The search for papers was performed by a single researcher. Study se-  
432 lection, on the other hand, was performed by two researchers. First, one  
433 researcher examined all found studies. Next, another researcher re-examined  
434 all studies classified as primary studies in addition to 20 randomly selected  
435 excluded studies to ensure the quality of the selection.

436 To ensure the quality of the review, the quality evaluation and data ex-  
437 traction was performed independently by two researchers. Inter-rater anal-  
438 ysis was performed using Krippendorff’s Alpha statistics [28, 29].

### 439 5.1. Data Sources and Search Strategy

440 This SLR was designed based on the guidelines by Kitchenham [30]. First  
441 a trial search in electronic databases was conducted. In order to scale the  
442 review to a manageable, yet sufficient size, databases were searched with  
443 different search strings. Relevant papers that were found during the trial

Table 2: Review activities.

Review phase		Researchers involved
Trial search in databases		A
Develop review protocol		A
Evaluate review protocol		B
Paper search and selection from databases	Search in databases	A
	Search string validation	A
	Selection based on metadata	A and B
	Selection based on full text	A and B
Pilot data extraction (3 papers)		A
Paper selection from the reference lists	Selection based on metadata	A and B
	Selection based on full text	A and B
Data extraction		A and B
Data synthesis		A

A – Cumulative voting	E – hundred dollar method
B – 100 dollar method	F – hundred dollar test
C – 100 dollar test	G – hundred point method
D – 100 point method	

444 search were used to extract additional search strings. The trial search re-  
 445 vealed that the number of studies that use CV is not very large. Therefore,  
 446 we decided to include not only software engineering studies but also studies  
 447 in other research areas, such as forestry or corporate governance, since one  
 448 key aspect we intended to investigate was analysis methods for CV.

449 Since CV is frequently used in studies without mentioning this in the  
 450 abstract, full text search in databases is preferable. Unfortunately not all  
 451 databases support full text search. Full text search was performed in the  
 452 IEEE Xplore and Springer Link databases. In ACM Digital Library, In-  
 453 spec/Compendex, ISI Web of Knowledge, and SCOPUS only metadata was  
 454 searched. Search strings consisting of a Boolean expression (A or B or C or  
 455 D or E or F or G), where:

456 Search strings contained only synonyms of CV and they did not limit the  
 457 research area to software engineering. The search was performed indepen-  
 458 dently using each of the search strings in each database. All search results  
 459 were combined and documented using reference management software. The  
 460 quality of the search strings and the selection of electronic databases were  
 461 validated against a previously known core set of papers—[3, 31, 10, 32]—  
 462 checking that all papers from the core set were found by the search.

## 463 5.2. Study Selection

464 To select relevant papers a set of criteria were designed. The criteria for  
 465 paper selection are presented in Tables 3 and 4.

466 Papers were selected in two phases: based on metadata and based on full  
 467 text.

468 Obviously, the main criterion for inclusion of a paper is that it must  
 469 present empirical use of CV or present an analysis of the results of using  
 470 CV. However, there are papers that pass this criterion but are not relevant  
 471 for this review. CV is frequently used in computer algorithms. There is  
 472 a significant difference between the way that humans and computers make  
 473 decisions. Since this review is concerned with human decisions we excluded  
 474 papers that present CV that is not performed by humans. In addition, only  
 475 papers that were written in English were selected and duplicate studies were  
 476 automatically excluded by the citation management software used in this  
 477 review.

Table 3: Paper search and selection in the databases.

Selection phase	Inclusion criteria	Number of papers selected
Search in databases	published from 2001 until 2011 (databases last accessed Feb. 20, 2011)	256
	contains search strings	
Selection based on metadata	exclude duplicates and tables of contents	177
	written in English	
Selection based on full text	full text is available	127
	study involves empirical use of CV or presents analysis of empirical use of CV	58
	CV is done by humans and not software	25

Table 4: Paper selection from the reference lists of the selected papers.

Selection phase	Inclusion criteria	Number of papers selected
Selection from references	papers included in the reference lists of relevant papers found in databases	467
Selection based on metadata	written in English	462
	reference is already revealed by search in databases	450
Selection based on full text	full text is available	329
	study involves empirical use of CV or presents analysis of empirical use of CV	15
	CV is done by humans and not software	

### 478 5.3. *Quality Evaluation*

479 The goal of quality evaluation is to determine the best primary studies  
480 according to some measure of quality. Since the number of studies that use  
481 CV is not large, quality evaluation was not used as an exclusion criterion.

482 Study quality obviously depends on the correctness of the study process  
483 including planning, operation, analysis and interpretation of the results (is  
484 the study right?) The correctness of the process can be measured by evalu-  
485 ating the description of the study or replicating the study. Thus, to gain the  
486 trust of industry practitioners and other researchers, the process of the study  
487 should be rigorously described. In short, the description has to facilitate the  
488 replication of the study as well as the presentation of limitations and validity  
489 threats.

490 Even the most correct and rigorously described study is useless if it does  
491 not contribute to the industry or research community (is it the right study?)  
492 The topic of the research ought to address important goals and issues. The  
493 findings of the study should also be significant, i.e. there is a high probability  
494 of the results of the study are true. The significance of the findings depends  
495 on how realistic the study is, the correctness of the process and the results  
496 of the study, as well as the statistical significance of the findings.

497 **Realism** of a study depends on the context, scale, and subjects of the  
498 study. The study should be conducted in a **setting** that is similar or equal  
499 to the setting in which the findings of the study are intended to be used.  
500 Hence, studies that are conducted in an industrial setting are in many cases  
501 valuable. The **subjects** of a study should be similar to the people who are  
502 supposed to use the findings of the study. The subjects ought to have appro-  
503 priate work experience, role in the organization, skills, cultural background,  
504 motivation, and so forth. The **scale** of a study refers to the size of the study  
505 objects. In the case of this systematic review the scale of a study is mea-  
506 sured as the number of prioritization items. Study in academia may have a  
507 large number of prioritization items. At the same time, an industrial study,  
508 with professionals as subjects, may involve a smaller number of prioritization  
509 items.

510 Each study may have a different level of realism. Some studies involve  
511 industry practitioners in an academic setting to simulate real word practice in  
512 a laboratory environment. Other studies may involve academic researchers  
513 that execute a project. For example, researchers may be developing open  
514 source software. On the reality scale these studies are somewhere in between  
515 the purely academic and industrial studies.

516 The **type** of the research study can be considered as a criterion for the  
517 evaluation of study realism. Reference [33] suggest that study designs that

are more rigorous (e.g. experiments) are more realistic than observational studies (e.g. case study) due to a higher level of control. On the other hand [34] rate study designs based on other criteria, i.e. how frequently each type of study design is used in an industrial or academic setting. If a study design is used more in an industrial setting, then it is considered more realistic. For instance, in software engineering, case studies are frequently used in industrial settings, whereas, experiments are usually performed in academia using students as subjects. Therefore, [34] argue that case studies are more realistic than formal experiments. Obviously the effect of study design on the study realism may be interpreted in different ways. Therefore, we will not use this parameter in our quality evaluation.

The statistical significance of the results of a study can be used to evaluate the significance of the study findings. This measure will not be used, because the studies that are evaluated belong to very different research areas, i.e. the significance levels of the findings of the studies are not directly comparable for meta-analysis. Additionally, sometimes, if study results do not conform to the expectations of researchers, no result is more interesting than a significant result. This may reveal important gaps in existing knowledge.

The ultimate goal of research, at least in software engineering, is in many cases industry impact. However, most of the time ideas need to be developed and validated in academia before industry professionals will risk to adopt them. Therefore, academic impact is important as well. Academic impact is usually measured by the number of citations. Academic impact is also measured for particular researchers, using the number of papers she has published and the number of citations of her papers. This measure will not be used in our quality evaluation because it is somewhat biased. The number of citations is likely to be lower for newer papers and the number of papers that a researcher has published gives little information about the actual quality or impact of her research.

### 5.3.1. Rating of the Studies

The quality evaluation in our review is based on the evaluation of: (i) Study realism. (ii) Study scale. (iii) Availability of raw results of CV. (iv) Quality of the research methodology.

Realism of the studies is rated in three aspects: subjects, setting, and scale. The subjects and setting is rated according to Table 5. The total rating of study realism is determined by summing up the ratings of the two aspects. For instance, if a study is conducted with industry professionals as subjects in an academic context the study will receive rating 1 (out of 2 maximal points).

Table 5: Rating of study reality level

Aspect	Contribute to relevance (rating 1)	Do not contribute to relevance (rating 0)
Subjects	Industry professionals	Academia students or teachers, or other
Context	Industrial	Academia

557 In order to rate the scale of a study the number of prioritization items  
558 was counted. If a paper presents several prioritization cases only the prior-  
559 itization with the largest number of the prioritization items is considered.  
560 If HCV is used all of the prioritization items on different levels are counted  
561 together. However, if an item is present in several groups in the hierarchy it  
562 is counted only once.

563 The availability of raw results of CV is rated separately because it is  
564 especially important for our purposes (and for most other researchers in  
565 order to replicate a study). The data availability rating criteria is given in  
566 Table 6. If the data of a study are not available it is not possible to validate  
567 the results of the study and, hence, the credibility of the findings is lower.  
568 Ideally the data collected in the study should be presented directly in the  
569 paper. An alternative may be to make the data freely available online and  
570 reference the online source.

571 The quality of the research methodology of a paper is rated according to  
572 a checklist presented in Appendix C. The checklist is based on guidelines  
573 for presenting research studies as presented in [35, 36] and the guidelines for  
574 quality evaluation of research studies presented in [34, 30]. Evaluation is done  
575 with regard to the rigor of the description and correctness of the research  
576 process and reasoning. Checklist items represent issues that research studies  
577 should implement and present in research paper. The checklist also contains  
578 item descriptions or questions that are used to evaluate the quality. Each  
579 item in the checklist is rated according to criteria presented in Table 7. The  
580 final rating of correctness of the research process of a study is computed by  
581 summing up the ratings assigned to all items in the checklist.

582 Study rating criteria was validated during a trial data extraction. Two  
583 researchers each rated three randomly selected papers. Afterwards, differ-  
584 ences in ratings were discussed and study rating criteria were updated to  
585 avoid differences in interpretation.

586 As a result of the rating each study was assigned four rating values on an  
587 ordinal scale. In order to perform a more advanced analysis of the quality  
588 evaluation results these ratings were then converted into ratio scale ranks.  
589 For each study, the number of studies that have received lower ratings is

Table 6: Research data availability rating

Rating	Study rating criteria
0	CV results was not provided in the paper and we was unable to obtain the results from the authors.
1	CV results are not provided in the paper but the data was obtained from the authors. Part of the data is lost or corrupted.
2	CV results are not provided in the paper but all the data was obtained from the authors.
3	All CV results are included in the paper or reference is given to online source where all the data can be accessed.

Table 7: Rating of correctness of research process

Rating	Study rating criteria
0	No description provided.
1	Only basic information is provided about the checklist item. Or significant validity threats exist with regard to this item.
2	Description is sufficient. Some minor questions are left unanswered. Validity threats may exist but they are not likely to affect the results of the study.
3	Description is rigorous and clear. Questions presented in quality evaluation checklist in Appendix C are answered. Decisions of the study are well justified, alternatives are discussed. No unhandled validity threats can be identified.

counted. The resulting number is the rank of the study; thereby, the quality of a study is expressed as four rank values.

An example of rating values is shown in Table 8. Table 9 shows ranking values computed for the studies in Table 8. We can observe that study realism level rating for ST3 is 0. There are no studies that have a lower study realism. Therefore, realism ranking for ST3 is 0. ST1 on the other hand has the highest realism rating. Since ST1 has higher reality level than both ST2 and ST3 it is assigned reality level rank 2.

#### 5.4. Data Extraction

The goal of data extraction is to understand how and why CV is used and how CV results are analysed in research studies. Ultimately, this will allow us to answer the first and second research questions in our study.

Table 8: Example of rating values

Study	Realism	Research data availability	Correctness of research process	Number of prioritization items
ST1	2	0	15	6
ST2	1	3	20	69
ST3	0	3	10	6

Table 9: Example of ranking values

Study	Reality level	Research data availability	Correctness of research process	Number of prioritization items
ST1	2	0	1	0
ST2	1	1	2	2
ST3	0	1	0	0

Data extraction was documented with the help of spreadsheet software. Extracted data items are available from [37].

## 6. Equality of Cumulative Votes

In the previous section we described the execution of the systematic literature review. In order to perform a more thorough analysis later we here present the design of ECV before presenting the results of the systematic literature review. For the results of the evaluation of ECV please see Section 7.3 (ECV is implemented in the *R* programming language [38] and the code can be found at [39].)

In CV stakeholders may assign similar or equal values to several prioritization items. As a result the difference between the items is small. The variation in priorities is caused not only by the difference between prioritization items but also by human error and lack of information for decision making. For instance, people tend to simplify the task of prioritization by assigning rounded values to items or giving equal values to several items [40].

During prioritization it may be beneficial to know which items are equal. A common example is software release planning where requirements are distributed among several product releases. If two or more requirements are considered equal they can be freely interchanged between the releases, and other criteria, such as cost or effort, may be used as sole indicators for planning that particular release.

### 6.1. Testing Equality of Two Items

There are two ways to determine which prioritization items have similar priority. One approach is to find items that are different and consider other items as equal. Another approach is to find items that are equal.

The first approach uses statistical tests to evaluate differences between e.g. two population means, in order to determine that two items are different. Populations in this case consist of priorities assigned by all stakeholders to a particular prioritization item. The number of stakeholders that perform the

631 prioritization is frequently small. Hence, the size of the sample is very often  
632 too small for statistical tests to detect a significant difference in the tests,  
633 thus, identify too many equal items to make any useful conclusions.

634 ECV, in contrast, uses the second approach. It finds items that are  
635 similar and the rest of the items are considered different. This method tests  
636 the probability of the difference between the means of two items being smaller  
637 than the given value. In short, ECV tests the probability of the means of two  
638 prioritization items differing by less than 25%. If the probability is higher  
639 than 70% the items are considered equal.

640 The input to ECV is an  $n \times p$  matrix  $A$  that contains the raw results of  
641 the prioritization. The columns of the matrix represent prioritization items  
642 while rows represent stakeholders. ECV performs the following operations  
643 for the priorities of each of the two prioritization items:

- 644 1. Replace zeroes in CV results.
- 645 2. Transform the data using *ilr* transformation.
- 646 3. Determine distribution function using kernel density estimation.
- 647 4. Use the distribution function to find the probability that the difference  
648 between two prioritization items is smaller than 25%.
- 649 5. Form groups of equal prioritization items.

650 Since CV results are compositional data, zeroes in  $A$  are replaced with  
651 other values. This is done using the multiplicative replacement strategy  
652 which is described in Section 2.4.1. Next, two columns are extracted from  
653 matrix  $A$  to create the new matrix  $B$ :

$$B = [a_{*,k} a_{*,l}], \quad (6)$$

654 where  $a$  is an element of matrix  $A$ , and  $k$  and  $l$  are the columns that repre-  
655 sent items that are tested for equality, "\*" denotes all rows of corresponding  
656 column.

657 The *ilr* transformation is then applied to each row of the matrix  $B$  and  
658 the new vector  $C$  is obtained. The equation for calculating elements of  $C$   
659 using *ilr* transformation is:

$$c_i = ilr(b_{i1}, b_{i2}) = \sqrt{0.5} \log(b_{i1}/b_{i2}), \quad (7)$$

660 where  $c_i$  is the  $i^{th}$  element of  $C$  and  $b_{i1}$  and  $b_{i2}$  are the first and second  
661 elements in the  $i^{th}$  row of  $B$ . Each value  $c_i$  represents a log-ratio between  $k$   
662 and  $l$ . The mean of the values of  $C$  can be interpreted as an average log-ratio  
663 between the items that expresses the difference between the items.

664 After the data is transformed into log-ratios statistical test can be ap-  
 665 plied. The purpose of the test is to determine what the probability is of the  
 666 relative difference between two prioritization items  $k$  and  $l$  being less than  
 667 25%. Or in terms of log-ratios it means determining the probability of  $c_i$   
 668 (obtained from priorities assigned to  $k$  and  $l$ ) as being in the range of  $\frac{3}{4}$  to  $\frac{4}{3}$ .  
 669 Hence, the objective of the test is to determine the probability of the sample  
 670 mean (i.e. mean value of the items of  $C$ ) laying between the two values.

671 The probability that the mean takes a particular value can be expressed  
 672 in the form of a cumulative distribution function. The probability of the  
 673 mean being between two values  $a$  and  $b$  (where  $a$  is smaller than  $b$ ) can be  
 674 determined by subtracting the probability of the mean being smaller than  $a$   
 675 from probability of the mean being smaller than  $b$ .

676 However, CV result data may or may not have multivariate normal distri-  
 677 bution. If the data is normally distributed a Student's  $t$  distribution function  
 678 can be used.

679 Otherwise a non-parametric estimation of the distribution function could  
 680 be performed. In our case, the CV result data obtained from the primary  
 681 studies identified by the systematic review, were tested for normality using  
 682 the Anderson-Darling test. Before applying the test the data was trans-  
 683 formed using methods of compositional data analysis. To compute the test  
 684 we used method *adtestWrapper* from  $R$  language library *robCompositions*.

685 The tests we performed indicated, quite strongly, that in most of the  
 686 prioritization cases the data is not normally distributed. Hence, our recom-  
 687 mendation is that, in general, a non-parametric approach should be used to  
 688 determine the probability density function, and one such, common, approach  
 689 would be to use the kernel density estimation. (In our implementation of  
 690 ECV in the  $R$  programming language, kernel density estimation is performed  
 691 using the package *ks*.)

692 To determine the probability of  $\bar{x}$  being between  $a$  and  $b$  the following  
 693 equation is used:

$$p = P(b) - P(a), \quad (8)$$

694 where  $P$  is the cumulative distribution function obtained by applying  
 695 kernel density estimation on *ilr*-transformed priority values denoted by vec-  
 696 tor  $C$ . Variable  $a$  is equal to *ilr*(3, 4) and  $b$  is equal to *ilr*(4, 3). (A graphical  
 697 interpretation of Equation (8) is presented in Figure 5.) The area that is  
 698 denoted by letter  $p$  represents the probability computed by the equation.

699 After both prioritization items are tested for equality it may be conve-  
 700 nient to display the equality of different items in the form of a table. Please

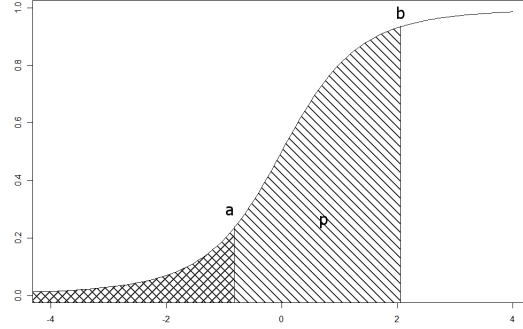

Figure 5: Cumulative distribution function of the log-ratio  $c_i$  between the items  $k$  and  $l$  (area  $p$  denotes probability that  $c_i$  is between  $\frac{3}{4}$  and  $\frac{4}{3}$ .)

Table 10: Example of equality table

prioritization items	i1	i2	i3	i4
i1	equal	equal	-	equal
i2	equal	equal	-	-
i3	-	-	equal	-
i4	equal	-	-	equal

see Table 10 for an example.

## 6.2. Grouping Prioritization Items

When equal items are determined they can be divided into groups of equal items. Division is performed in such a way that each two items in a group are equal. The test for equality of the items described in Section 6.1 is not transitive. Hence, if prioritization item  $A$  is equal to  $B$  and  $B$  is equal to  $C$  then it does not automatically imply that  $A$  is equal to  $C$ . Therefore, there may be several ways to group the equal items. The two possible division criteria that we have considered in this study are:

1. Maximize the number of items that have a group.
2. Maximize the number of items in each group.

## 7. Results

This section presents the results of this study including the systematic literature review and the application of ECV on industry and academic data collected from the primary studies. Data extracted from primary studies and the results of the quality evaluation are available in [37].

717 *7.1. State of Practice in Empirical Studies that use CV or Analyze the Re-*  
718 *sults of CV (RQ 1)*

719 The study search resulted in 634 unique studies. The search in databases  
720 revealed 180 papers, while an additional 454 papers were discovered us-  
721 ing snowball sampling. The study selection resulted in 40 primary studies.  
722 Hence, 94% of the studies were excluded by the selection criteria. Snowball  
723 sampling revealed 15 or 36% out of all primary studies. The study selection  
724 criteria and the number of papers excluded by each criterion are shown in  
725 Tables 3 and 4. In total 163 of 634 studies were excluded because full text  
726 was not available.

727 All results of the study selection are available online and can be obtained  
728 by contacting the authors of this paper. For each study we specify keywords  
729 and databases that were used to find the study. If a study has been excluded,  
730 the exclusion criteria are provided.

731 The number of papers revealed by each search string and database is  
732 presented in Table 11. It should be noted that several papers were found  
733 by more than one search string or in more than one database. Table 11  
734 shows that the search string ‘cumulative voting’ was the most frequently  
735 used in research community to denote CV. Therefore, researchers should use  
736 or reference this term when discussing CV.

737 To perform snowball sampling we examined the references of primary  
738 studies that were found during the database search. References were used  
739 to search for the papers in the Google and Google Scholar search engines.  
740 Studies that were found in the search and passed the study selection criteria  
741 were added to the set of primary studies.

742 After the primary studies were selected, data extraction and quality eval-  
743 uation was performed by two researchers. One researcher examined all stud-  
744 ies while the second researcher did quality evaluation and data extraction for  
745 10% of the studies. The studies were randomly selected. Inter-rater agree-  
746 ment were calculated by means of Krippendorff’s alpha coefficient. Agree-  
747 ment for data extraction results was 0.86 and agreement for the quality  
748 evaluation was 0.73. According to [29] it is common to require agreement  
749 above 0.8 and the lowest acceptable agreement is 0.667. Therefore, we con-  
750 clude that the agreement calculated for this study is sufficient. Ratings of  
751 the study setting, correctness, research data availability, and number of pri-  
752 oritization items are presented in Figure 6.

753 Table 12 shows the studies with the highest quality according to our cri-  
754 teria. These studies show a high level of rigor in a realistic setting. Moreover,  
755 authors of the studies manifest confidence by providing raw data for further  
756 use and evaluation.

Figure 7 shows a bubble chart of the distribution of studies over research areas and time. The figure shows that CV was first applied some time ago in research of government elections. Nowadays, though, CV has been adopted in a wide range of software engineering areas. Most frequently in requirements engineering and software release planning. Eight studies use CV as a research method while the remaining 32 studies report on using CV in industry.

765 *7.2. CV Result Analysis Methods Identified by RQ 1 (RQ 2)*

766 The papers identified in the review use various CV result analysis meth-  
767 ods. The main goals for CV result analysis are presented in Table 13 and  
768 a summary of methods used in the primary studies can be found in Section  
769 Appendix B.

770 In order to present prioritization results many studies use charts or tables.  
771 These charts and tables show the average priority of each prioritization item  
772 that is computed from priorities assigned by all stakeholders. In [48] a table  
773 of five items with highest total priority is presented. [49] shows tables with  
774  $min$ ,  $max$ ,  $\tilde{x}$ ,  $\bar{x}$  and  $\sigma$  of priorities assigned by different stakeholders to a  
775 particular prioritization item. Finally, in [50, 49] error bars are added to the  
776 chart of final priorities (denoting  $\sigma$  of priorities).

777 In a few cases final priorities are presented in the form of ranks and  
778 CV results are degraded from ratio to ordinal scale. This is done when the  
779 interest lies only in the order of final priorities.

780 Several papers are interested in the difference between priorities from dif-  
781 ferent prioritization perspectives (e.g. current and ideal situation) or stake-  
782 holder groups (e.g. software developers and management). Pearson or Spear-  
783 man correlation coefficients are commonly used to determine what the level of  
784 similarity is between all priorities from two perspectives. Whereas, Wilcoxon,  
785 Kruskal-Wallis, Nemenyi-Damico-Wolfe-Dunn tests and the  $\chi^2$  statistic are  
786 used to detect if there is a significant difference in the value of one prioritiza-  
787 tion item from two or more perspectives. In addition, PCA is used to detect  
788 if there are distinct groups of stakeholders with common priorities [7, 10, 51].

789 In some cases, a stakeholder may assign equal priority to several prioritiza-  
790 tion items or leave several items unrated, e.g. the stakeholder may not have  
791 carefully considered all prioritization items. Hence, the difference between  
792 the items may have been unnoticed.

793 In [4] the scalability of prioritization is measured using two charts. The  
794 first chart shows the average percentages of items given a non-zero value.  
795 The second chart shows average percentages of divergence of values. If a  
796 stakeholder assigns equal priorities to many prioritization items the diver-  
797 gence of values is low. Unfortunately it is unclear from [4] how the average  
798 percentage of divergence is calculated.

799 In [52] distribution, disagreement, and satisfaction charts are presented.  
800 The distribution chart shows how the final value of a prioritization item is  
801 constructed from priorities assigned by different stakeholders. This chart  
802 shows how much each stakeholder has contributed to the final value of a  
803 prioritization item. The disagreement chart shows the level of agreement be-  
804 tween different stakeholders on the value of a particular prioritization item.

Table 13: Goals for CV result analysis.

Purpose of the method	Name
Show the final priority of each prioritization item. Stakeholder priorities are combined into one value.	Chart or table of final priorities
Difference between priorities assigned by different perspectives (status quo, ideal situation) or different stakeholder groups (developers, management) [10]	Bi-plot
detect stakeholder groups with similar priorities [10]	Bi-plot
show the relative number of issues that have received high, medium, or low priority [10]	Ternary plot
detect stakeholder groups with common priorities [10]	PCA
how the final value of prioritization item is constructed from priorities assigned by different stakeholder. This chart shows how much each stakeholder has contributed to the final value of prioritization item [52]	Distribution chart
the level of agreement between different stakeholders on value of particular prioritization item [52]	Disagreement chart
satisfaction of a stakeholder with the prioritization results by the calculating correlation between the final priorities and priorities assigned by a stakeholder [52]	Satisfaction chart
percentage of the divergence of the priorities assigned by a stakeholder [4]	average percentage of divergence
average percentage of items given a non-zero value [4]	
detect equal prioritization items (presented in this paper)	ECV

805 The satisfaction chart shows stakeholder satisfaction with prioritization re-  
806 sults by calculating the correlation between final priorities and priorities  
807 assigned by a stakeholder.

808 The use of bi-plots and ternary plots are proposed in [10]. A bi-plot shows  
809 final priorities and stakeholder viewpoints in a two dimensional plane while a  
810 ternary plot shows prioritization items inside a triangle. Ternary plots show  
811 how many low, medium or high priorities are assigned to a prioritization  
812 item. The corners of the triangle represent high, medium, and low priority,  
813 e.g. if a prioritization item has received mostly high priority values then it  
814 is shown closer to the high priority corner.

#### 815 7.2.1. Problems with Data Analysis in Primary Studies

816 A few primary studies, as revealed by the systematic review, have prob-  
817 lems with the data analysis. These studies disregard the compositional na-  
818 ture of CV results.

819 In [51, 7] standard PCA is performed without applying log-ratio trans-  
820 formations to compositional data. According to [53], this is likely to be  
821 inadequate and in [54], a more appropriate method for performing PCA of  
822 compositional data is shown.

823 The normality of compositional data is defined in [55]. It is stated that

Table 14: Identified groups of equal items.

Paper identifier & Description	Type of CV	Pairs of equal items	Groups of equal items
Barney 2009 [42] Perceived priorities of software product investments in an ideal situation	comp. HCV	(A2, B4) (B4, B5) (B4, C1) (B5, B15) (B6, B7) (B7, B8) (B14, B15) (B14, B18) (B17, B18)	(A2, B4) (B4, C1) (B5, B15) (B6, B7) (B14, B15) (B17, B18)
	uncomp. HCV	(B4, B5) (B4, B8) (B5, B15) (B6, B7) (B7, B12) (B14, B15) (B14, B18) (B16, B17) (B12, B13)	(B4, B5) (B5, B15) (B6, B7) (B14, B15) (B16, B17) (B12, B13)
Berander 2009 [17] Software requirements for course management system	uncomp. & comp. HCV	(3:2, 3:3)	(3:2, 3:3)
Svahnberg 2008 [47] The view of academia researchers on the requirements understandability criteria	CV	(Development, Verification & Validation) (Development, Product Planning 1)	(Development, Product Planning 1)

824 it is convenient to transform compositional data using isometric log-ratio  
825 transformation before the tests for normality can be applied. [48] violates  
826 this requirement by applying the Shapiro-Wilk test for normality to untrans-  
827 formed compositional data.

828 The Kruskal-Wallis test is used in [48] to analyze compositional data.  
829 The test is used to evaluate the difference between three organization levels.  
830 The Kruskal-Wallis test assumes that variables within each sample are in-  
831 dependent [56]. However, values within compositional data vectors are not  
832 independent (as described in Section 2.4). Hence, we claim the Kruskal-  
833 Wallis test to be somewhat misused in [48].

### 834 7.3. Identifying Prioritization Items with Equal Priority Using ECV (RQ 3)

835 This section presents the results of applying ECV to the industrial and  
836 academic CV data as found through the systematic literature review. Six  
837 primary studies included the raw prioritization results in the paper itself or

838 referenced online sources where the data was available. To collect the data  
839 from the remaining 34 papers, the authors of all papers were contacted.

840 First, the email addresses provided in the papers were used. If no answer  
841 was received authors were searched for using Google, Facebook and LinkedIn.  
842 Authors from 11 papers provided us with data to be used in the evaluation  
843 of ECV. However, due to confidentiality reasons we can not publish this data  
844 directly and instead urge interested parties to contact the authors directly.

845 In short, ECV was applied to 27 CV prioritization cases from 14 stud-  
846 ies. In the cases of HCV, ECV was applied two times to the same data  
847 to test both compensated and uncompensated priorities. Equal items were  
848 detected in three prioritization cases. A summary of the results is presented  
849 in Table 14.

850 In [47] a prioritization of requirement understandability criteria is pre-  
851 sented. One of the main findings of paper [47] is that from an academic  
852 viewpoint Development and Verification and Validation are more important  
853 than other criteria. ECV adds new knowledge to these results. It shows that  
854 Development and Verification and Validation are equally important, i.e. it is  
855 not true that either one of the criteria is more important.

856 A prioritization of software requirements for an academic course man-  
857 agement system is presented in [17]. ECV detected that two features—  
858 Assignment Submission and Assignment Feedback—have the same priority.  
859 If the system is developed in several releases Assignment Submission and As-  
860 signment Feedback features can be freely interchanged between the releases  
861 and, hence, in this way ECV simplifies release planning.

862 In [42] software product investments are prioritized with HCV. The re-  
863 sults of ECV was different for uncompensated and compensated HCV. When  
864 compensated HCV was used ECV detected equal items that belonged to dif-  
865 ferent high level prioritization groups (*A*, *B* and *C*), indicating that ECV  
866 provided a more fine-grained view. In the case of uncompensated HCV, on  
867 the other hand, all equal items belonged to one high level prioritization group  
868 (group *B*).

## 869 8. Discussion and Conclusions

870 This section discusses the results of the systematic review and evaluation  
871 of ECV conducted as part of this study.

872 CV has been applied in various areas, but most frequently in requirements  
873 prioritization and release planning, and quite often also as part of research  
874 methodologies. A large part of the studies have been conducted in Sweden,  
875 at Ericsson AB. One can see a slight increase in the interest in CV. During

876 the last five years there have been more studies that use CV than between,  
877 say, year 2000–2005.

878 Overall, studies that use CV or analyze the results of CV have a high  
879 quality in terms of correctness of research process and study realism. How-  
880 ever, very few studies present prioritization of more than 30 items and the  
881 availability of research data is somewhat limited. In our particular case we  
882 were able to obtain data from 43% of the primary studies.

### 883 *8.1. Implications for Practitioners*

884 The results of this study provide decision support for industry practi-  
885 tioners. We believe that a collection of state of the practice studies help  
886 the adoption of CV prioritization method. (Top studies are summarized in  
887 Table 12.) In addition, a set of CV analysis methods enables comprehen-  
888 sive understanding of the prioritization results. (The analysis methods are  
889 presented in Table 13.) One of the most common goals of CV analysis is to  
890 display of the prioritization results and, thus, to show the difference between  
891 several prioritization perspectives.

892 Additionally, we present ECV—a novel method for CV analysis. Priori-  
893 tization often results in the assignment of similar priorities to several prior-  
894 itization items. CV results contain both ‘real priorities’ and random errors.  
895 Due to random errors, equal prioritization items may receive different pri-  
896 orities. ECV identifies such items. It allows stakeholders to disregard the  
897 random part of the CV results. Thus, ECV simplifies the understanding of  
898 the prioritization results.

899 ECV identifies prioritization items with similar priority and tests whether  
900 these items can be considered equal. In this case, ECV can be used in  
901 software release planning. For example, let us suppose that a set of software  
902 requirements are prioritized with regard to the implementation costs. First  
903 of all, ECV can then detect items with equal cost. Second, the equal items  
904 can be freely swapped between the releases. Finally, the decision to allocate  
905 a requirement to a particular release can be made based on another criteria,  
906 such as risk or business value.

907 ECV has been successfully applied on a considerable amount of CV data  
908 and, additionally, has also detected equal items in different groups of HCV  
909 hierarchies.

### 910 *8.2. Implications for Academia*

911 In the systematic review 36% of papers were revealed by the snowball  
912 sampling. That is a considerable amount. Several studies do not mention the  
913 name of the prioritization method (i.e. cumulative voting or hundred dollar

914 test). Others are not available through selected databases because they are  
915 conference publications or theses. It shows, in our opinion, that snowball  
916 sampling ought to be used in all systematic literature reviews.

917 CV results are a special type of data—compositional data. Standard  
918 statistical analysis methods that assume the independence of the samples  
919 cannot be applied to CV results. In [57] methods for the analysis of com-  
920 positional data have been presented. The systematic review conducted as a  
921 part of this study revealed that 22 studies analyze CV results; yet, only one  
922 study uses compositional data analysis methods, i.e. [10]. None of the stud-  
923 ies, including [10], present methods for detecting items with equal priority  
924 in CV results. Hence, ECV is, in this respect, a unique method.

925 The small use of compositional data analysis is really not surprising, since  
926 literature describing CV does not state that the results are compositional  
927 data. Standard statistical analysis methods may produce useful results for  
928 compositional data. However, there are cases when they are misleading or  
929 even faulty. Section 7.2.1 contains evidence of inappropriate use of statistical  
930 methods by several papers.

931 This study has collected a set of compositional data analysis methods for  
932 CV analysis (see Table 13). We believe that this could help researchers to  
933 improve the analysis of CV results with appropriate methods.

934 Since CV is associated with compositional data, it might be tempting to  
935 choose another requirements prioritization method. However, it would not  
936 solve the problem *per se*, because any ratio scale prioritization, for instance  
937 AHP, contains compositional data.

938 The principal implications for the academia are mainly the following:

- 939 1. All systematic literature reviews should include snowball sampling.
- 940 2. Researchers can improve their statistical analysis of CV results using  
941 compositional data analysis methods collected and developed by this  
942 study.
- 943 3. When CV or any other ratio scale prioritization method is taught,  
944 compositional data analysis should also be presented as part of the  
945 solution.

### 946 8.3. *Validity Threats*

947 The validity of the systematic review is mainly limited by the chosen  
948 databases, the design of the review, and human judgement in study selection  
949 and data extraction.

950 To mitigate the threats we use the most popular databases in the field  
951 of software engineering. In the beginning of the systematic review a re-  
952 view protocol was developed, peer-reviewed, and revised. Search strategy

953 was validated against a set of previously known papers obtained from other  
954 researchers. One of many terms used to name cumulative voting is ‘\$100  
955 method’. We were not able to search for this term because none of the cho-  
956 sen databases support search for special characters like ‘\$’ and the search  
957 string ‘100 method’ yields hundreds of thousands of results. To increase the  
958 likelihood of discovering relevant studies snowball sampling was extensively  
959 used.

960 To increase the validity of study selection, all included studies and 20  
961 randomly selected excluded studies were examined by two researchers. There  
962 were no disagreement on the inclusion/exclusion of the studies.

963 The large number of studies identified by snowball sampling (15 out of  
964 40 studies) may be caused by faulty design or by faulty execution of the  
965 search in the databases. There are several reasons why the studies revealed  
966 by snowball sampling are not revealed by the search in databases. Reason  
967 for each study is given in Table Appendix A.2. Based on these reasons we  
968 argue that snowball sampling does not indicate any problems with the design  
969 of the search in the databases.

970 Four studies were not found because they were not available through  
971 databases used in this systematic review. Out of them one is a master  
972 thesis, two are conference publications and one is a publication in the area  
973 of forestry. Seven studies do not mention the name of the prioritization  
974 method (i.e. hundred dollar method or cumulative voting). Only phrases  
975 like “distribution of a predefined amount of fictitious money (\$100,000) over  
976 the items to be prioritized” or “1,000 points” allowed us to identify that CV  
977 was indeed used. One paper used a previously unknown name for CV, i.e.  
978 the 100-point technique.

979 The quality of the data extraction and quality evaluation was validated  
980 using inter-rater agreement analysis. In our case, 10% of the studies were  
981 rated by two researchers and Krippendorff’s alpha was calculated. The agree-  
982 ment for the data extraction results was 0.86 and the agreement for the  
983 quality evaluation was 0.73 (indicating a credible level of quality).

984 There are two main validity threats with ECV itself. First, ECV may not  
985 detect prioritization items with equal priority. Second, ECV may produce a  
986 false positive result. There may be a real difference between items that ECV  
987 claims as being equal.

988 To mitigate the first threat ECV was applied on artificially created test  
989 data with and without items with similar priority. ECV worked correctly in  
990 both cases.

991 To mitigate the second threat we visually inspected the results of the  
992 application of ECV on the real world data from the primary studies. We

concluded that items identified by ECV can be considered equal.

CV results used in the evaluation of ECV were tested for normality. The tests indicated that CV results do not have multivariate normal distribution. Therefore, the design of ECV was based on a non-parametric statistical test.

#### 8.4. Future Research

There are very few studies that apply CV on prioritization sets of more than 30 items. However, in requirements engineering, industry practitioners need to prioritize much larger numbers of software requirements. Therefore, the state of art could benefit from the application of CV and HCV to large prioritization sets.

The proposed method, ECV, has now been evaluated on existing research data. To further evaluate the ECV, it could be applied in direct industry practice and in prioritization cases with a larger number of prioritization items. Additionally, compositional data analysis methods, as the ones identified by this paper, should be tried with other prioritization methods that produce ratio scale results.

#### 8.5. Conclusions

CV prioritization results are special type of data – compositional data. Any analysis of CV results must take into account the compositional nature of the CV results.

This study presents a systematic literature review of the empirical use of CV. CV has been applied in various areas, but most frequently in requirements prioritization and release planning. The review has resulted in a collection of state of the practice studies and CV result analysis methods. We believe that it can help the adoption of CV prioritization method.

In our case, snowball sampling was performed as a part of the review. Since it revealed 36% out of all primary studies, we believe that in future snowball sampling should be used in all systematic reviews.

Additionally, we present ECV—a novel method for CV analysis. As suggested by our evaluation, ECV is able to detect prioritization items with equal priority (i.e. items that have insignificant difference in priority). The evaluation of ECV was based on the data obtained from the authors of the primary studies.

## 1323 Appendix A. Primary Studies

### 1324 Appendix A.1. Primary studies found during search in databases.

	Title	Reference
	Prioritizing countermeasures through the countermeasure method for software security (CM-Sec)	Baca 2010 [58]
	The relative importance of aspects of intellectual capital for software companies	Barney 2009 [41]
	Software product quality: Ensuring a common goal	Barney 2009 [8]
	Balancing software product investments	Barney 2009 [42]
	Hierarchical cumulative voting (HCV) prioritization of requirements in hierarchies	Berander 2006 [4]
	A goal question metric based approach for efficient measurement framework definition	Berander 2006 [31]
	Evaluating two ways of calculating priorities in requirements hierarchies: An experiment on hierarchical cumulative voting	Berander 2009 [17]
	Election systems and voter turnout: Experiments in the United States	Bowler 2001 [59]
	A low information theory of ballot position effect	Brockington 2003 [60]
	Prioritization of issues and requirements by cumulative Voting: A compositional data analysis framework	Chatzipetrou 2010 [10]
	A comparison of cumulative voting and generalized plurality voting	Cooper 2010 [61]
	Challenges with software verification and validation activities in the space industry	Feldt 2010 [46]
1325	Investigating impact of business risk on requirements selection decisions	Fogelstrom 2009 [62]
	Choosing the right prioritization method	Hatton 2008 [63]
	Early prioritization of goals	Hatton 2007 [64]
	Rigorous support for flexible planning of product releases: A stakeholder-centric approach and its initial evaluation	Heikkilä 2010 [65]
	Voting methods in strategic forest planning: Experiences from Metsähallitus	Hiltunen 2008 [13]
	Empirical extension of a classification framework for addressing consistency in model based development	Kuzniarz 2010 [49]
	Evaluation of the multi-criteria approval method for timber-harvesting group decision support	Laukkanen 2005 [44]
	A practitioner's guide to light weight software process assessment and improvement planning	Pettersson 2008 [7]
	An empirical study on views of importance of change impact analysis issues	Rovegard 2008 [50]
	An industrial case study on the choice between language customization mechanisms	Staron 2006 [66]
	Perspectives on requirements understandability—For whom does the teacher's bell toll?	Svahnberg 2008 [47]
	A study on the importance of order in requirements prioritization	Svahnberg 2009 [16]
	A structured goal based measurement framework enabling traceability and prioritization	Touseef 2010 [67]

1326 *Appendix A.2. Primary studies revealed by snowball sampling.*

1327

Reference	Title	Reason why the paper is not revealed by the search in databases
Ahl 2005 [3]	An experimental comparison of five prioritization methods	Selected databases does not contain the paper, master thesis at BTH
Barney 2008 [43]	A product management challenge: Creating software product value through requirements selection	Prioritization method name not mentioned, phrase "1,000 points" used instead.
Berander 2004 [68]	Differences in views between development roles in software process improvement—A quantitative comparison	Prioritization method name not mentioned, phrase "100 points" used instead.
Berander 2004 [69]	Using students as subjects in requirements prioritization	Unknown CV name: 100-point technique
Berander 2003 [70]	Identification of key factors in software process management: A case study	Prioritization method name not mentioned, phrase "100 points" used instead.
Cole 1990 [71]	Cumulative voting in a municipal election: A note on voter reactions and electoral consequences	Study published before year 2001.
Hu 2006 [45]	Adding value to software requirements: An empirical study in the chinese software industry	Prioritization method name not mentioned, phrase "1,000 points" used instead.
Jonsson 2005 [9]	A study on prioritization of impact analysis issues: A comparison between perspectives	Selected databases does not contain the paper.
Jonsson 2005 [48]	Understanding impact analysis: An empirical study to capture knowledge on different organizational levels	Selected databases does not contain the paper.
Kuklinski 1973 [72]	Cumulative and plurality voting: An analysis of Illinois' unique electoral system	Study published before year 2001.
Laukkanen 2004 [73]	Applying voting theory in participatory decision support for sustainable timber harvesting	Selected databases does not contain the paper.
Regnell 2001 [32]	An industrial case study on distributed prioritization in market-driven requirements engineering for packaged software	Prioritization method name not mentioned: "distribution of a predefined amount of fictitious money (\$100,000) over the items to be prioritized."
Regnell 2000 [52]	Visualization of agreement and satisfaction in distributed prioritization of market requirements	Prioritization method name not mentioned: "distribution of a predefined amount of fictitious money (\$100,000) over the items to be prioritized."
Wohlin 2006 [74]	Game theory and cumulative voting in Illinois: 1902–1954	Study published before year 2001.
Wohlin 2006 [51]	Criteria for selecting software requirements to create product value: An industrial empirical study	Prioritization method name not mentioned: "The subjects had 1,000 points to spend among the 13 criteria."

## Appendix B. CV Result Analysis Methods

	Paper																					
	Svalinberg2008	Svalinberg2009	Starr2006	Petersson2008	Wohlitz2006	Laukkonen2005a	Hu2006	Jonsson2005a	Kuzmar2010	Rowgard2008	Bernard2006a	Bernard2004a	Bernard2006	Feldt2010	Barney2009b	Barney2008	Barney2009a	Barney2009	Jonsson2005	Chatzipetrou2010	Reguel2001	Reguel2000
Analysis method																						
Table that shows final priorities	x			x													x					
Chart that shows final priorities	x			x	x	x											x					
Table of top-5 prioritization items																						
$min$ , $max$ , $\bar{x}$ , $\bar{x}$ and $\sigma$ of priorities assigned by different stakeholders									x		x											
Bar chart of prioritization results showing $\bar{x}$ priority and $\sigma$ of priorities									x	x												
Pearson correlation coefficient		x										x										
Nemenyi-Damico-Wolfe-Dunn														x								
Spearman's $r$															x							
Kruskal-Wallis								x							x		x					
Wilcoxon							x															
Correlation matrix		x													x		x					
Chart for comparing priorities from two perspectives, priorities are points in two dimensional plane, $x$ - and $y$ -axis represent two different perspectives										x									x			
Difference between priorities assigned by each two stakeholders using $\chi^2$ -statistic										x												
Median ranks		x																				
CV results converted to priority ranks		x											x						x			
PCA				x	x															x		
Percentage of divergence of priorities assigned by a stakeholder											x											
Average percentage of items given non-zero value											x											
Distribution chart																					x	x
Disagreement chart				x																	x	x
Satisfaction chart			x																		x	x
Bi-plot																					x	
Ternary plot																					x	

## Appendix C. Quality Evaluation Checklist

Item	Question or Description of the Item	Rating
1. Background, introduction	Introduce research area	
2. Problem statement, purpose	What is the problem [36]? Where does it occur [30]? Who has observed it [36]? Why is it important to be solved [36]?	
3. Context, independent variables (aka. environment, setting)	Study location, time constraints, application domain, organization, tools, market, process (e.g. software development methodology), size of project, product that is being developed	
4. Related work	Other existing work, alternative technologies, solutions, and studies	
5. Goals and Hypotheses	Null hypothesis and one or more alternative hypotheses for each goal	
6. Research questions		
7. Design, Research methods		
7.1. Design	Description of each step of the study	
7.2. Control group	If there is a control group, are participants similar to the treatment group participants in terms of variables that may affect study outcomes[30]?	
7.3. Randomization	Random selection of participants and objects Random assignment of treatment and objects to participants Random order of treatments in case of paired design. If each participant is assigned two treatments A and B, then part of participants perform A first and the other part start with B	
7.4. Blocking	Group participants of the study into homogeneous groups called blocks (e.g. students in one course, database developers in one company) and implement the study design within each block independently. The idea is that variability of independent variables (e.g. experience and knowledge of subjects) is smaller within a group. That helps measuring changes in dependent variables [33].	
7.5. Balancing	Equal number of subjects should be assigned to each treatment [33].	
7.6. Blinding	Automated assignment of treatments to subjects [33] Automated distribution of study materials to subjects [33] Persons who grade the task results should not know which treatment was used [33] Analyst should not know which treatment group is which [33] Automated data collection from subjects [33]	
8. Subjects (participants)		
8.1. Population		
8.2. Sampling	How sampling is performed? What subjects are included and excluded? [30] What is the type of the sampling (e.g. convenience, random)? Is the sample(selected participants) representative of the population?	
8.3. "Drop outs" and response rate	Are reasons given for refusal to participate[30]?	
8.4. Subject motivation	E.g. material benefits, course credits for students, etc.	
9. Objects	E.g. documents and other artifacts	
10. Measures, Data collection procedures	Who, when, and how to measure [30]? How is the measurement supported? Is it automated [30]? Are the measures used in the study the most relevant ones for answering the research questions [30]?	
11. Analysis procedure		
11.1. Data description	Do the numbers add up across different tables and subgroups [30]?	
11.2. Data types (continuous, ordinal, categorical)		
11.3. Scoring systems		
11.4. Data set reduction, outliers		
11.5. Statistical methods	Are the assumptions of statistical methods met? What statistical programs are used?	
11.6. Statistical significance	If statistical tests are used to determine differences, is the actual p-value given [30]? If the study is concerned with differences among groups, are confidence limits given describing the magnitude of any observed differences [30]?	
12. Validity threats	Threats, implications of the threats, and threat mitigation	
12.1. Side-effects during study execution	Deviations from the plan, solutions for the deviations	
13. Most important findings	Are all study questions answered [30]? Are negative findings presented [30]?	
14. Industry impact, inference, generalization	What implications does the report have for practice [30]? How and where the results can be used? Limitations under which findings are relevant [36]?	
15. Future work
